`+,repgrid,repgrid-method` *Concatenate repgrid objects.*

Description

Simple concatenation of repgrid objects or list containing repgrid objects using the '+' operator.

Usage

```
## S4 method for signature 'repgrid,repgrid'
e1 + e2

## S4 method for signature 'list,repgrid'
e1 + e2

## S4 method for signature 'repgrid,list'
e1 + e2
```

Arguments

e1,e2	A repgrid object.

Details

Methods for "+" function.

Author(s)

Mark heckmann

Examples

```
x <- bell2010
x + x
x + list(x,x)
list(x,x) + x
```

---

addConstruct — *Add a new construct to an existing grid object.*

Description

Add a new construct to an existing grid object.

Usage

```
addConstruct(x, l.name = NA, r.name = NA, scores = NA, l.preferred = NA,
  r.preferred = NA, l.emerged = NA, r.emerged = NA, position = NA,
  side = "pre")
```

Arguments

- `x` — `repgrid` object.
- `l.name` — Name of the left pole (character string).
- `r.name` — Name of the right pole (character string).
- `scores` — Numerical ratings for the new construct row (length must match number of elements in the grid).
- `l.preferred` — Is the left one the preferred pole? (logical).
- `r.preferred` — Is the right one the preferred pole? (logical).
- `l.emerged` — Is the left one the emergent pole? (logical).
- `r.emerged` — Is the right one the emergent pole? (logical).
- `position` — An integer at which row the construct will be added. TODO. Does not work properly.
- `side` — Not yet in use.

Value

`repgrid` object.

Author(s)

Mark Heckmann

`addElement`

Examples

```
## Not run:

   # show grid
   bell2010
   addConstruct(bell2010, "left pole", "pole right", c(3,1,3,2,5,4,6,3,7,1))

## End(Not run)
```

addElement *Add an element to an existing grid.*

Description

Add an element to an existing grid.

Usage

```
addElement(x, name = NA, scores = NA, abbreviation = NA, status = NA,
  position = NA, side = "pre")
```

Arguments

x	repgrid object.
name	Name of the new element (character string).
scores	Numerical ratings for the new element column (length must match number of constructs in the grid).
abbreviation	Abbreviation for element name.
status	Element status (not yet in use).
position	An integer at which column the element will be added. TODO: Does not work properly yet.
side	Not yet in use.

Value

repgrid object

addConstruct

Examples

```
## Not run:

   bell2010
   addElement(bell2010, "new element", c(1,2,5,4,3,6,5,2,7))

## End(Not run)
```

alignByIdeal *Align constructs using the ideal element to gain pole preferences.*

Description

The direction of the constructs in a grid is arbitrary and a reflection of a scale does not affect the information contained in the grid. Nonetheless, the direction of a scale has an effect on inter-element correlations (Mackay, 1992) and on the spatial representation and clustering of the grid (Bell, 2010). Hence, it is desirable to follow a protocol to align constructs that will render unique results. A common approach is to align constucts by pole preference, i. e. aligninig all positive and negative poles. This can e. g. be achieved using `swapPoles`. If an ideal element is present, this element can be used to identify the positive and negative pole. The function `alignByIdeal` will align the constructs accordingly. Note that this approach does not always yield definite results as sometimes ratings do not show a clear preference for one pole (Winter, Bell & Watson, 2010). If a preference cannot be determined definitely, the construct direction remains unchanged (a warning is issued in that case).

Usage

```
alignByIdeal(x, ideal, high = TRUE)
```

Arguments

`x`	`repgrid` object
`ideal`	Number of the element that is used for alignment (the ideal).
`high`	Logical. Whether to align the constructs so the ideal will have high ratings on the constructs (i.e. `TRUE`, default) or low ratings (`FALSE`). High scores will lead to the preference pole on the right side, low scores will align the preference pole on the left side.

Value

`repgrid` object with aligned constructs.

alignByLoadings *Align constructs by loadings on first pricipal component.*

Description

In case a construct loads negatively on the first principal component, the function alignByLoadings will reverse it so that all constructs have positive loadings on the first principal component (see deatil section for more).

Usage

```
alignByLoadings(x, trim = 20, index = TRUE)
```

Arguments

x	repgrid object.
trim	The number of characters a construct is trimmed to (default is 10). If NA no trimming is done. Trimming simply saves space when displaying the output.
index	Whether to print the number of the construct (e.g. for correltion matrices). The default is TRUE.

Details

The direction of the constructs in a grid is arbitrary and a reflection of a scale does not affect the information contained in the grid. Nonetheless, the direction of a scale has an effect on inter-element correlations (Mackay, 1992) and on the spatial representation and clustering of the grid (Bell, 2010). Hence, it is desirable to follow a protocol to align constructs that will render unique results. A common approach is to align constructs by pole preference, but this information is not always accessible. Bell (2010) proposed another solution for the problem of construct alignment. As a unique protocol he suggests to align constructs in a way so they all have positive loadings on the first component of a grid PCA.

Value

An object of class `alignByLoadings` containing a list of calculations with the following entries:

- `cor.before` Construct correlation matrix before reversal
- `loadings.before` Loadings on PCs before reversal
- `reversed` Constructs that have been reversed
- `cor.after` Construct correlation matrix after reversal
- `loadings.after` Loadings on PCs after reversal

Note

Bell (2010) proposed a solution for the problem of construct alignment. As construct reversal has an effect on element correlation and thus on any measure that based on element correlation (Mackay, 1992), it is desireable to have a standard method for construct alignment independently from its semantics (preferred pole etc.). Bell (2010) proposes to align constructs in a way so they all have positive loadings on the first component of a grid PCA.

bertin *Make Bertin display of grid data.*

Description

One of the most popular ways of displaying grid data has been adopted from Bertin's (1974) graphical proposals, which have had an immense influence onto data visualization. One of the most appealing ideas presented by Bertin is the concept of the reordable matrix. It is comprised of graphical displays for each cell, allowing to identify structures by eye-balling reordered versions of the data matrix (see Bertin, 1974). In the context of repertory grids, the display is made up of a simple colored rectangle where the color denotes the corresponding score. Bright values correspond to low, dark to high scores. For an example of how to analyze a Bertin display see e.g. Dick (2000) and Raeithel (1998).

Usage

```
bertin(x, colors = c("white", "black"), showvalues = TRUE, xlim = c(0.2,
  0.8), ylim = c(0, 0.6), margins = c(0, 1, 1), cex.elements = 0.7,
  cex.constructs = 0.7, cex.text = 0.6, col.text = NA, border = "white",
  lheight = 0.75, id = c(T, T), cc = 0, cr = 0, cc.old = 0,
  cr.old = 0, col.mark.fill = "#FCF5A4", print = TRUE, ...)
```

Arguments

x	repgrid object.
colors	Vector. Two or more colors defininig the color ramp for the bertin (default c("white", "black")).
showvalues	Logical. Wether scores are shown in bertin
xlim	Vector. Left and right limits inner bertin (default c(.2, .8)).
ylim	Vector. Lower and upper limits of inner bertin default(c(.0, .6)).
margins	Vector of length three (default margins=c(0,1,1)). 1st element denotes the left, 2nd the upper and 3rd the right margin in npc coordinates (i.e. 0 to zero).
cex.elements	Numeric. Text size of element labels (default .7).
cex.constructs	Numeric. Text size of construct labels (default .7).
cex.text	Numeric. Text size of scores in bertin cells (default .7).
col.text	Color of scores in bertin (default NA). By default the color of the text is chosen according to the background color. If the background ist bright the text will be black and vice versa. When a color is specified the color is set independetn of background.
border	Border color of the bertin cells (default white).

`lheight`	Line height for constructs.
`id`	Logical. Wheteher to print id number for constructs and elements respectively (default `c(T,T)`).
`cc`	Numeric. Current column to mark.
`cr`	Numeric. Current row to mark.
`cc.old`	Numeric. Column to unmark.
`cr.old`	Numeric. Row to unmark.
`col.mark.fill`	Color of marked row or column (default `"#FCF5A4"`).
`print`	Print whole bertin. If `FALSE` only current and old row and column are printed.
`...`	Optional arguments to be passed on to `bertinBase`.

Value

`NULL` just for the side effects, i.e. printing.

   bertin(feixas2004, id=c(F, F))

   bertin(feixas2004, cc=3, cr=4)
   bertin(feixas2004, cc=3, cr=4, col.mark.fill="#e6e6e6")

## End(Not run)
```

bertinCluster	*Bertin display with corresponding cluster anaylsis.*

Description

Element columns and constructs rows are ordered according to cluster criterion. Various distance measures as well as cluster methods are supported.

Usage

```
bertinCluster(x, dmethod = c("euclidean", "euclidean"), cmethod = c("ward",
  "ward"), p = c(2, 2), align = TRUE, trim = NA, type = c("triangle"),
  xsegs = c(0, 0.2, 0.7, 0.9, 1), ysegs = c(0, 0.1, 0.7, 1), x.off = 0.01,
  y.off = 0.01, cex.axis = 0.6, col.axis = grey(0.4), draw.axis = TRUE,
  ...)
```

Arguments

`x`	`repgrid` object.
`dmethod`	The distance measure to be used. This must be one of `"euclidean"`, `"maximum"`, `"manhattan"`, `"canberra"`, `"binary"`, or `"minkowski"`. Default is `"euclidean"`. Any unambiguous substring can be given (e.g. `"euc"` for `"euclidean"`). A vector of length two can be passed if a different distance measure for constructs and elements is wanted (e.g.`c("euclidean", "manhattan")`). This will apply euclidean distance to the constructs and manhattan distance to the elements. For additional information on the different types see `?dist`.
`cmethod`	The agglomeration method to be used. This should be (an unambiguous abbreviation of) one of `"ward"`, `"single"`, `"complete"`, `"average"`, `"mcquitty"`, `"median"` or `"centroid"`. Default is `"ward"`. A vector of length two can be passed if a different cluster method for constructs and elements is wanted (e.g.`c("ward", "euclidean")`). This will apply ward clustering to the constructs and single linkage clustering to the elements. If only one of either constructs or elements is to be clustered the value `NA` can be supplied. E.g. to cluster elements only use `c(NA, "ward")`.
`p`	The power of the Minkowski distance, in case `"minkowski"` is used as argument for `dmethod`. `p` can be a vector of length two if different powers are wanted for constructs and elements respectively (e.g. `c(2,1)`).
`align`	Whether the constructs should be aligned before clustering (default is `TRUE`). If not, the grid matrix is clustered as is. See Details section in function `cluster` for more information.
`trim`	The number of characters a construct is trimmed to (default is `10`). If `NA` no trimming is done. Trimming simply saves space when displaying the output.
`type`	Type of dendrogram. Either or `"triangle"` (default) or `"rectangle"` form.
`xsegs`	Numeric vector of normal device coordinates (ndc i.e. 0 to 1) to mark the widths of the regions for the left labels, for the bertin display, for the right labels and for the vertical dendrogram (i.e. for the constructs).

`ysegs`	Numeric vector of normal device coordinates (ndc i.e. 0 to 1) to mark the heights of the regions for the horizontal dendrogram (i.e. for the elements), for the bertin display and for the element names.
`x.off`	Horizontal offset between construct labels and construct dendrogram and (default is `0.01` in normal device coordinates).
`y.off`	Vertical offset between bertin display and element dendrogram and (default is `0.01` in normal device coordinates).
`cex.axis`	`cex` for axis labels, default is `.6`.
`col.axis`	Color for axis and axis labels, default is `grey(.4)`.
`draw.axis`	Whether to draw axis showing the distance metric for the dendrograms (default is `TRUE`).
`...`	additional parameters to be passed to function `bertin`.

Value

A list of two `hclust` object, for elements and constructs respectively.

`cluster`

Examples

```
## Not run:

   # default is euclidean distance and ward clustering
   bertinCluster(bell2010)

   ### applying different distance measures and cluster methods

   # euclidean distance and single linkage clustering
   bertinCluster(bell2010, cmethod="single")
   # manhattan distance and single linkage clustering
   bertinCluster(bell2010, dmethod="manhattan", cm="single")
   # minkowksi distance with power of 2 = euclidean distance
   bertinCluster(bell2010, dm="mink", p=2)

   ### using different methods for constructs and elements

   # ward clustering for constructs, single linkage for elements
   bertinCluster(bell2010, cmethod=c("ward", "single"))
   # euclidean distance measure for constructs, manhatten
   # distance for elements
   bertinCluster(bell2010, dmethod=c("euclidean", "man"))
   # minkowski metric with different powers for constructs and elements
```

```
    bertinCluster(bell2010, dmethod="mink", p=c(2,1)))

    ### clustering either constructs or elements only
    # euclidean distance and ward clustering for constructs no
    # clustering for elements
    bertinCluster(bell2010, cmethod=c("ward", NA))
    # euclidean distance and single linkage clustering for elements
    # no clustering for constructs
    bertinCluster(bell2010, cm=c(NA, "single"))

    ### changing the appearance
    # different dendrogram type
    bertinCluster(bell2010, type="rectangle")
    # no axis drawn for dendrogram
    bertinCluster(bell2010, draw.axis=F)

    ### passing on arguments to bertin function via ...
     # grey cell borders in bertin display
    bertinCluster(bell2010, border="grey")
    # omit printing of grid scores, i.e. colors only
    bertinCluster(bell2010, showvalues=FALSE)

    ### changing the layout
    # making the vertical dendrogram bigger
    bertinCluster(bell2010, xsegs=c(0, .2, .5, .7, 1))
    # making the horizontal dendrogram bigger
    bertinCluster(bell2010, ysegs=c(0, .3, .8, 1))

## End(Not run)
```

---

bindConstructs *Concatenate the constructs of two or more grids.*

Description

I.e. the constructs are combined to form one long grid. The girds must have the same set of elements and an identical scale range. The order of the elements may differ.

Usage

```
bindConstructs(..., index = FALSE)
```

Arguments

`...`	One or more repgrid objects or a list containing `repgrid` object.
`index`	TODO. Logical (default `TRUE`). Whether to add an index at the end of each construct name so it remains clear from which grid each construct came.

Details

This function can be used in order to analyse multiple grids as one 'big grid' (eg. Slater, 1977, chap. 11).

Value

`repgrid` object with concatenated constructs.

Author(s)

Mark Heckmann

References

Slater, P. (1977). *The measurement of intrapersonal space by grid technique*. London: Wiley.

Examples

```
a <- randomGrid()
 b <- randomGrid()
 b@elements <- rev(a@elements)   # reverse elements
 bindConstructs(a, b)
 bindConstructs(a, b, a)

 # using lists of repgrid objects
 bindConstructs(a, list(a, b))
```

`biplot2d` *Draw a two-dimensional biplot.*

Description

The biplot is the central way to create a joint plot of elements and constructs. Depending on te parameters chosen it contains information on the distances between elements and constructs. Also the relative values the elements have on a construct can be read off by projetion the element onto the construct vector. A lot of parameters can be changed rendering different types of biplots (ESA, Slater's) and different looks (colors, text size). See the example section below to get started.

Usage

```
biplot2d(x, dim = c(1, 2), map.dim = 3, center = 1, normalize = 0,
  g = 0, h = 1 - g, col.active = NA, col.passive = NA,
  e.point.col = "black", e.point.cex = 0.9, e.label.col = "black",
  e.label.cex = 0.7, e.color.map = c(0.4, 1), c.point.col = "black",
  c.point.cex = 0.8, c.label.col = "black", c.label.cex = 0.7,
  c.color.map = c(0.4, 1), c.points.devangle = 91, c.labels.devangle = 91,
  c.points.show = TRUE, c.labels.show = TRUE, e.points.show = TRUE,
  e.labels.show = TRUE, inner.positioning = TRUE,
```

```
outer.positioning = TRUE, c.labels.inside = FALSE, c.lines = TRUE,
col.c.lines = grey(0.9), flipaxes = c(FALSE, FALSE), strokes.x = 0.1,
strokes.y = 0.1, offsetting = TRUE, offset.labels = 0, offset.e = 1,
axis.ext = 0.1, mai = c(0.2, 1.5, 0.2, 1.5), rect.margins = c(0.01,
0.01), srt = 45, cex.pos = 0.7, xpd = TRUE, unity = FALSE,
unity3d = FALSE, scale.e = 0.9, zoom = 1, var.show = TRUE,
var.cex = 0.7, var.col = grey(0.1), ...)
```

Arguments

`x`	`repgrid` object.
`dim`	Dimensions (i.e. principal components) to be used for biplot (default is `c(1,2)`).
`map.dim`	Third dimension (depth) used to map aesthetic attributes to (default is `3`).
`center`	Numeric. The type of centering to be performed. 0= no centering, 1= row mean centering (construct), 2= column mean centering (elements), 3= double-centering (construct and element means), 4= midpoint centering of rows (constructs). The default is `1` (row centering).
`normalize`	A numeric value indicating along what direction (rows, columns) to normalize by standard deviations. `0 = none, 1= rows, 2 = columns` (default is `0`).
`g`	Power of the singular value matrix assigned to the left singular vectors, i.e. the constructs.
`h`	Power of the singular value matrix assigned to the right singular vectors, i.e. the elements.
`col.active`	Columns (elements) that are no supplementary points, i.e. they are used in the SVD to find principal components. default is to use all elements.
`col.passive`	Columns (elements) that are supplementary points, i.e. they are NOT used in the SVD but projecte into the component space afterwards. They do not determine the solution. Default is `NA`, i.e. no elements are set supplementary.
`e.point.col`	Color of the element symbols. The default is `"black"`. Two values can be entered that will create a color ramp. The values of `map.dim` are mapped onto the ramp. If only one color color value is supplied (e.g. `"black"`) no mapping occurs and all elements will have the same color irrespective of their value on the `map.dim` dimension.
`e.point.cex`	Size of the element symbols. The default is `.9`. Two values can be entered that will create a size ramp. The values of `map.dim` are mapped onto the ramp. If only one color size value is supplied (e.g. `.8`) no mapping occurs and all elements will have the same size irrespective of their value on the `map.dim` dimension.
`e.label.col`	Color of the element label. The default is `"black"`. Two values can be entered that will create a color ramp. The values of `map.dim` are mapped onto the ramp. If only one color color value is supplied (e.g. `"black"`) no mapping occurs and all labels will have the same color irrespective of their value on the `map.dim` dimension.
`e.label.cex`	Size of the element labels. The default is `.7`. Two values can be entered that will create a size ramp. The values of `map.dim` are mapped onto the ramp. If

only one color size value is supplied (e.g. .7) no mapping occurs and all labels will have the same size irrespective of their value on the map.dim dimension.

e.color.map
: Value range to determine what range of the color ramp defined in e.color will be used for mapping the colors. Default is c(.4, ,1). Usually not important for the user.

c.point.col
: Color of the construct symbols. The default is "black". Two values can be entered that will create a color ramp. The values of map.dim are mapped onto the ramp. If only one color color value is supplied (e.g. "black") no mapping occurs and all construct will have the same color irrespective of their value on the map.dim dimension.

c.point.cex
: Size of the construct symbols. The default is .8. Two values can be entered that will create a size ramp. The values of map.dim are mapped onto the ramp. If only one color size value is supplied (e.g. .8) no mapping occurs and all construct will have the same size irrespective of their value on the map.dim dimension.

c.label.col
: Color of the construct label. The default is "black". Two values can be entered that will create a color ramp. The values of map.dim are mapped onto the ramp. If only one color color value is supplied (e.g. "black") no mapping occurs and all labels will have the same color irrespective of their value on the map.dim dimension.

c.label.cex
: Size of the construct labels. The default is .7. Two values can be entered that will create a size ramp. The values of map.dim are mapped onto the ramp. If only one color size value is supplied (e.g. .7) no mapping occurs and all labels will have the same size irrespective of their value on the map.dim dimension.

c.color.map
: Value range to determine what range of the color ramp defined in c.color will be used for mapping. Default is c(.4, ,1). Usually not important for the user.

c.points.devangle
: The deviation angle from the x-y plane in degrees. These can only be calculated if a third dimension map.dim is specified. Only the constructs that do not depart more than the specified degrees from the x-y plane will be printed. This facilitates the visual interpretation, as only vectors represented near the current plane are shown. Set the value to 91 (default) to show all vectors.

c.labels.devangle
: The deviation angle from the x-y plane in degrees. These can only be calculated if a third dimension map.dim is specified. Only the labels of constructs that do not depart more than the specified degrees from the x-y plane will be printed. Set the value to 91 (default) to show all construct labels.

c.points.show
: Whether the constructs are printed (default is TRUE). FALSE will surpress the printing of the constructs. To only print certain constructs a numeric vector can be provided (e.g. c(1:10)).

c.labels.show
: Whether the construct labels are printed (default is TRUE). FALSE will surpress the printing of the labels. To only print certain construct labels a numeric vector can be provided (e.g. c(1:10)).

e.points.show
: Whether the elements are printed (default is TRUE). FALSE will surpress the printing of the elements. To only print certain elements a numeric vector can be provided (e.g. c(1:10)).

e.labels.show
: Whether the element labels are printed (default is TRUE). FALSE will surpress the printing of the labels. To only print certain element labels a numeric vector can be provided (e.g. c(1:10)).

inner.positioning
: Logical. Whether to calculate positions to minimize overplotting of elements and construct labels (default isTRUE). Note that the positioning may slow down the plotting.

outer.positioning
: Logical. Whether to calculate positions to minimize overplotting of of construct labels on the outer borders (default isTRUE). Note that the positioning may slow down the plotting.

c.labels.inside
: Logical. Whether to print construct labels next to the points. Can be useful during inspection of the plot (default FALSE).

c.lines
: Logical. Whether construct lines from the center of the biplot to the sourrounding box are drawn (default is FALSE).

col.c.lines
: The color of the construct lines from the center to the borders of the plot (default is gray(.9)).

flipaxes
: Logical vector of length two. Whether x and y axes are reversed (default is c(F,F)).

strokes.x
: Length of outer strokes in x direction in NDC.

strokes.y
: Length of outer strokes in y direction in NDC.

offsetting
: Do offsetting? (TODO)

offset.labels
: Offsetting parameter for labels (TODO).

offset.e
: offsetting parameter for elements (TODO).

axis.ext
: Axis extension factor (default is .1). A bigger value will zoom out the plot.

mai
: Margins available for plotting the labels in inch (default is c(.2, 1.5, .2, 1.5)).

rect.margins
: Vector of length two (default is c(.07, .07)). Two values specifying the additional horizontal and vertical margin around each label.

srt
: Angle to rotate construct label text. Only used in case offsetting=FALSE.

cex.pos
: Cex parameter used during positioning of labels if prompted. Does usually not have to be changed by user.

xpd
: Logical (default is TRUE). Wether to extend text labels over figure region. Usually not needed by the user.

unity
: Scale elements and constructs coordinates to unit scale in 2D (maximum of 1) so they are printed more neatly (default TRUE).

unity3d
: Scale elements and constructs coordinates to unit scale in 3D (maximum of 1) so they are printed more neatly (default TRUE).

scale.e
: Scaling factor for element vectors. Will cause element points to move a bit more to the center. (but only if unity or unity3d is TRUE). This argument is for visual appeal only.

zoom
: Scaling factor for all vectors. Can be used to zoom the plot in and out (default 1).

var.show	Show explained sum-of-squares in biplot? (default TRUE).
var.cex	The cex value for the percentages shown in the plot.
var.col	The color value of the percentages shown in the plot.
...	parameters passed on to come.

Details

For the construction of a biplot the grid matrix is first centered and normalized according to the prompted options.
Next, the matrix is decomposed by singular value decomposition (SVD) into

$$X = UDV^T$$

The biplot is made up of two matrices

$$X = GH^T$$

These matrices are construed on the basis of the SVD results.

$$\hat{X} = UD^g D^h V^T$$

Note that the grid matrix values are only recovered and the projection property is only given if $g + h = 1$

---

biplot3d *Draw grid in rgl (3D device).*

Description

The 3D biplot opens an interactive 3D device that can be rotated and zoomed using the mouse. A 3D device facilitates the exploration of grid data as significant proportions of the sum-of-squares are often represented beyond the first two dimensions. Also, in a lot of cases it may be of interest to explore the grid space from a certain angle, e.g. to gain an optimal view onto the set of elements under investigation (e.g. Raeithel, 1998).

Usage

```
biplot3d(x, dim = 1:3, labels.e = TRUE, labels.c = TRUE, lines.c = TRUE,
  lef = 1.3, center = 1, normalize = 0, g = 0, h = 1,
  col.active = NA, col.passive = NA, c.sphere.col = grey(0.4),
  c.cex = 0.6, c.text.col = grey(0.4), e.sphere.col = grey(0),
  e.cex = 0.6, e.text.col = grey(0), alpha.sphere = 0.05,
```

```
col.sphere = "black", unity = FALSE, unity3d = FALSE, scale.e = 0.9,
zoom = 1, ...)
```

Arguments

`x`	`repgrid` object.
`dim`	Dimensions to display.
`labels.e`	Logical. whether element labels are displayed.
`labels.c`	Logical. whether construct labels are displayed.
`lines.c`	Numeric. The way lines are drawn through the construct vectors. `0` = no lines, `1` = lines from constructs to outer frame, `2` = lines from the center to outer frame.
`lef`	Construct lines extension factor
`center`	Numeric. The type of centering to be performed. 0= no centering, 1= row mean centering (construct), 2= column mean centering (elements), 3= double-centering (construct and element means), 4= midpoint centering of rows (constructs). Default is `1` (row centering).
`normalize`	A numeric value indicating along what direction (rows, columns) to normalize by standard deviations. `0 = none, 1= rows, 2 = columns` (default is `0`).
`g`	Power of the singular value matrix assigned to the left singular vectors, i.e. the constructs.
`h`	Power of the singular value matrix assigned to the right singular vectors, i.e. the elements.
`col.active`	Columns (elements) that are no supplementary points, i.e. they are used in the SVD to find principal components. default is to use all elements.
`col.passive`	Columns (elements) that are supplementary points, i.e. they are NOT used in the SVD but projecte into the component space afterwards. They do not determine the solution. Default is `NA`, i.e. no elements are set supplementary.
`c.sphere.col`	Color of construct spheres.
`c.cex`	Size of construct text.
`c.text.col`	Color for construct text.
`e.sphere.col`	Color of elements.
`e.cex`	Size of element labels.
`e.text.col`	Color of element labels.
`alpha.sphere`	Numeric. alpha blending of the sourrounding sphere (default`".05"`).
`col.sphere`	Color of sourrouding sphere (default`"black"`).
`unity`	Scale elements and constructs coordinates to unit scale (maximum of 1) so they are printed more neatly (default `TRUE`).
`unity3d`	To come.
`scale.e`	Scaling factor for element vectors. Will cause element points to move a bit more to the center (but only if `unity` or `unity3d` is `TRUE`). This argument is for visual appeal only.

zoom	Not yet used. Scaling factor for all vectors. Can be used to zoom the plot in and out (default 1).
...	Parameters to be passed on.

biplotEsa2d *Plot an eigenstructure analysis (ESA) biplot in 2D.*

Description

The ESA is a special type of biplot suggested by Raeithel (e.g. 1998). It uses midpoint centering as a default. Note that the eigenstructure analysis is just a special case of a biplot that can also be produced using the `biplot2d` function with the arguments `center=4, g=1, h=1`. Here, only the arguments that are modified for the ESA biplot are described. To see all the parameters that can be changed see `biplot2d`.

Usage

```
biplotEsa2d(x, center = 4, g = 1, h = 1, ...)
```

Arguments

`x`	`repgrid` object.
`center`	Numeric. The type of centering to be performed. 0= no centering, 1= row mean centering (construct), 2= column mean centering (elements), 3= double-centering (construct and element means), 4= midpoint centering of rows (constructs). Eigenstructure analyis uses midpoint centering (4).
`g`	Power of the singular value matrix assigned to the left singular vectors, i.e. the constructs. Eigenstructure analyis uses `g=1`.
`h`	Power of the singular value matrix assigned to the right singular vectors, i.e. the elements. Eigenstructure analyis uses `h=1`.
`...`	Additional parameters for be passed to `biplot2d`.

---

biplotPseudo3d *See biplotPseudo3d for its use. Draws a biplot of the grid in 2D with depth impression (pseudo 3D).*

Description

This version is basically a 2D biplot. It only modifies color and size of the symbols in order to create a 3D impression of the data points. This function will call the standard biplot2d function with some modified arguments. For the whole set of arguments that can be used see biplot2d. Here only the arguments special to biplotPseudo3d are outlined.

Usage

```
biplotPseudo3d(x, dim = 1:2, map.dim = 3, e.point.col = c("white",
  "black"), e.point.cex = c(0.6, 1.2), e.label.col = c("white", "black"),
  e.label.cex = c(0.6, 0.8), e.color.map = c(0.4, 1),
  c.point.col = c("white", "darkred"), c.point.cex = c(0.6, 1.2),
  c.label.col = c("white", "darkred"), c.label.cex = c(0.6, 0.8),
  c.color.map = c(0.4, 1), ...)
```

Arguments

x	repgrid object.
dim	Dimensions (i.e. principal components) to be used for biplot (default is c(1,2)).
map.dim	Third dimension (depth) used to map aesthetic attributes to (default is 3).
e.point.col	Color(s) of the element symbols. Two values can be entered that will create a color ramp. The values of map.dim are mapped onto the ramp. The default is c("white", "black"). If only one color color value is supplied (e.g. "black") no mapping occurs and all elements will have the same color irrespective of their value on the map.dim dimension.

e.point.cex
: Size of the element symbols. Two values can be entered that will represents the lower and upper size of a range of cex the values of `map.dim` are mapped onto. The default is `c(.6, 1.2)`. If only one cex value is supplied (e.g. `.7`) no mapping occurs and all elements will have the same size irrespective of their value on the `map.dim` dimension.

e.label.col
: Color(s) of the element labels. Two values can be entered that will create a color ramp. The values of `map.dim` are mapped onto the ramp. The default is `c("white", "black")`. If only one color color value is supplied (e.g. `"black"`) no mapping occurs and all element labels will have the same color irrespective of their value on the `map.dim` dimension.

e.label.cex
: Size of the element labels. Two values can be entered that will represents the lower and upper size of a range of cex the values of `map.dim` are mapped onto. The default is `c(.6, .8)`. If only one cex value is supplied (e.g. `.7`) no mapping occurs and all element labels will have the same size irrespective of their value on the `map.dim` dimension.

e.color.map
: Value range to determine what range of the color ramp defined in `e.color` will be used for mapping the colors. Default is `c(.4, ,1)`. Usually not important for the user.

c.point.col
: Color(s) of the construct symbols. Two values can be entered that will create a color ramp. The values of `map.dim` are mapped onto the ramp. The default is `c("white", "darkred")`. If only one color color value is supplied (e.g. `"black"`) no mapping occurs and all elements will have the same color irrespective of their value on the `map.dim` dimension.

c.point.cex
: Size of the construct symbols. Two values can be entered that will represents the lower and upper size of a range of cex the values of `map.dim` are mapped onto. The default is `c(.6, 1.2)`. If only one cex value is supplied (e.g. `.7`) no mapping occurs and all elements will have the same size irrespective of their value on the `map.dim` dimension.

c.label.col
: Color(s) of the construct labels. Two values can be entered that will create a color ramp. The values of `map.dim` are mapped onto the ramp. The default is `c("white", "black")`. If only one color color value is supplied (e.g. `"black"`) no mapping occurs and all construct labels will have the same color irrespective of their value on the `map.dim` dimension.

c.label.cex
: Size of the construct labels. Two values can be entered that will represents the lower and upper size of a range of cex the values of `map.dim` are mapped onto. The default is `c(.6, .9)`. If only one cex value is supplied (e.g. `.7`) no mapping occurs and all construct labels will have the same size irrespective of their value on the `map.dim` dimension.

c.color.map
: Value range to determine what range of the color ramp defined in `c.color` will be used for mapping. Default is `c(.4, ,1)`. Usually not important for the user.

...
: Additional parameters passed to `biplot2d`.

biplotSimple   *A graphically unsophisticated version of a biplot.*

Description

It will draw elements and constructs vectors using similar arguments as biplot2d. It is a version for quick exploration used during development.

Usage

```
biplotSimple(x, dim = 1:2, center = 1, normalize = 0, g = 0, h = 1 -
  g, unity = T, col.active = NA, col.passive = NA, scale.e = 0.9,
  zoom = 1, e.point.col = "black", e.point.cex = 1,
  e.label.col = "black", e.label.cex = 0.7, c.point.col = grey(0.6),
  c.label.col = grey(0.6), c.label.cex = 0.6, ...)
```

Arguments

`x`	`repgrid` object.
`dim`	Dimensions (i.e. principal components) to be used for biplot (default is `c(1,2)`).
`center`	Numeric. The type of centering to be performed. 0= no centering, 1= row mean centering (construct), 2= column mean centering (elements), 3= double-centering (construct and element means), 4= midpoint centering of rows (constructs). The default is `1` (row centering).
`normalize`	A numeric value indicating along what direction (rows, columns) to normalize by standard deviations. `0 = none, 1= rows, 2 = columns` (default is `0`).
`g`	Power of the singular value matrix assigned to the left singular vectors, i.e. the constructs.
`h`	Power of the singular value matrix assigned to the right singular vectors, i.e. the elements.
`unity`	Scale elements and constructs coordinates to unit scale in 2D (maximum of 1) so they are printed more neatly (default `TRUE`).
`col.active`	Columns (elements) that are no supplementary points, i.e. they are used in the SVD to find principal components. default is to use all elements.
`col.passive`	Columns (elements) that are supplementary points, i.e. they are NOT used in the SVD but projecte into the component space afterwards. They do not determine the solution. Default is `NA`, i.e. no elements are set supplementary.
`scale.e`	Scaling factor for element vectors. Will cause element points to move a bit more to the center. This argument is for visual appeal only.
`zoom`	Scaling factor for all vectors. Can be used to zoom the plot in and out (default `1`).
`e.point.col`	Color of the element symbols (default is `"black"`.
`e.point.cex`	Size of the element symbol (default is `1`.
`e.label.col`	Color of the element labels (default is `"black"`.
`e.label.cex`	Size of the element labels (default is `.7`.
`c.point.col`	Color of the construct lines (default is `grey(.6)`.
`c.label.col`	Color of the construct labels (default is `grey(.6)`.
`c.label.cex`	Size of the costruct labels (default is `.6`.
`...`	Parameters to be passed on to `center()` and `normalize`.

Value

`repgrid` object.

biplotSlater2d *Draws Slater's INGRID biplot in 2D.*

Description

The default is to use row centering and no normalization. Note that Slater's biplot is just a special case of a biplot that can be produced using the biplot2d function with the arguments `center=1, g=1, h=1`. The arguments that can be used in this function are the same as in biplot2d. Here, only the arguments that are set for Slater's biplot are described. To see all the parameters that can be changed see biplot2d.

Usage

```
biplotSlater2d(x, center = 1, g = 1, h = 1, ...)
```

Arguments

x	`repgrid` object.
center	Numeric. The type of centering to be performed. 0= no centering, 1= row mean centering (construct), 2= column mean centering (elements), 3= double-centering (construct and element means), 4= midpoint centering of rows (constructs). Slater's biplot uses 1 (row centering).

g	Power of the singular value matrix assigned to the left singular vectors, i.e. the constructs.
h	Power of the singular value matrix assigned to the right singular vectors, i.e. the elements.
...	Additional parameters for be passed to biplot2d.

biplotSlater3d *Draw the Slater's INGRID biplot in rgl (3D device).*

Description

The 3D biplot opens an interactive 3D device that can be rotated and zoomed using the mouse. A 3D device facilitates the exploration of grid data as significant proportions of the sum-of-squares are often represented beyond the first two dimensions. Also, in a lot of cases it may be of interest to explore the grid space from a certain angle, e.g. to gain an optimal view onto the set of elements under investigation (e.g. Raeithel, 1998). Note that Slater's biplot is just a special case of a biplot that can be produced using the biplot3d function with the arguments `center=1, g=1, h=1`.

Usage

```
biplotSlater3d(x, center = 1, g = 1, h = 1, ...)
```

Arguments

x	repgrid object.
center	Numeric. The type of centering to be performed. 0= no centering, 1= row mean centering (construct), 2= column mean centering (elements), 3= double-centering (construct and element means), 4= midpoint centering of rows (constructs). Default is 1 (row i.e. construct centering).
g	Power of the singular value matrix assigned to the left singular vectors, i.e. the constructs.
h	Power of the singular value matrix assigned to the right singular vectors, i.e. the elements.
...	Additional arguments to be passed to biplot3d.

   biplotSlater3d(boeker, e.cex=1)
   biplotSlater3d(boeker, col.sphere="red")

## End(Not run)
```

---

biplotSlaterPseudo3d *Draws Slater's biplot in 2D with depth impression (pseudo 3D).*

Description

The default is to use row centering and no normalization. Note that Slater's biplot is just a special case of a biplot that can be produced using the biplotPseudo3d function with the arguments center=1, g=1, h=1. Here, only the arguments that are modified for Slater's biplot are described. To see all the parameters that can be changed see biplot2d and biplotPseudo3d.

Usage

```
biplotSlaterPseudo3d(x, center = 1, g = 1, h = 1, ...)
```

Arguments

`x`	`repgrid` object.
`center`	Numeric. The type of centering to be performed. 0= no centering, 1= row mean centering (construct), 2= column mean centering (elements), 3= double-centering (construct and element means), 4= midpoint centering of rows (constructs). Slater's biplot uses 1 (row centering).
`g`	Power of the singular value matrix assigned to the left singular vectors, i.e. the constructs.
`h`	Power of the singular value matrix assigned to the right singular vectors, i.e. the elements.
`...`	Additional parameters for be passed to `biplotPseudo3d`.

```

`center` *Centering of rows (constructs) and/or columns (elements).*

Description

Centering of rows (constructs) and/or columns (elements).

Usage

```
center(x, center = 1, ...)
```

Arguments

x	repgrid object.
center	Numeric. The type of centering to be performed. 0= no centering, 1= row mean centering (construct), 2= column mean centering (elements), 3= double-centering (construct and element means), 4= midpoint centering of rows (constructs). of the scale(default FALSE). Default is 1 (row centering).
...	Not evaluated.

Value

matrix containing the transformed values.

Note

If scale midpoint centering is applied no row or column centering can be applied simultaneously. TODO: After centering the standard representation mode does not work any more as it remains unclear what color values to attach to the centered values.

Author(s)

Mark Heckmann

Examples

```
## Not run:

 center(bell2010)       # no centering
 center(bell2010, rows=T)   # row centering of grid
 center(bell2010, cols=T)   # column centering of grid
 center(bell2010, rows=T, cols=T) # row and column centering

## End(Not run)
```

---

cluster *Cluster analysis (of constructs or elements).*

Description

cluster is a preliminary implementation of a cluster function. It supports various distance measures as well as cluster methods. More is to come.

Usage

```
cluster(x, along = 0, dmethod = "euclidean", cmethod = "ward", p = 2,
  align = TRUE, trim = NA, main = NULL, mar = c(4, 2, 3, 15), cex = 0,
  lab.cex = 0.8, cex.main = 0.9, print = TRUE, ...)
```

Arguments

x	`repgrid` object.
along	Along which dimension to cluster. 1 = constructs only, 2= elements only, 0=both (default).
dmethod	The distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given. For additional information on the different types type `?dist`.
cmethod	The agglomeration method to be used. This should be (an unambiguous abbreviation of) one of `"ward"`, `"single"`, `"complete"`, `"average"`, `"mcquitty"`, `"median"` or `"centroid"`.
p	The power of the Minkowski distance, in case `"minkowski"` is used as argument for `dmethod`.
align	Whether the constructs should be aligned before clustering (default is `TRUE`). If not, the grid matrix is clustered as is. See Details section for more information.
trim	the number of characters a construct is trimmed to (default is `10`). If `NA` no trimming is done. Trimming simply saves space when displaying the output.
main	Title of plot. The default is a name indicating the distance function and cluster method.
mar	Define the plot region (bottom, left, upper, right).
cex	Size parameter for the nodes. Usually not needed.
lab.cex	Size parameter for the constructs on the right side.
cex.main	Size parameter for the plot title (default is `.9`).
print	Logical. Wether to print the dendrogram (default is `TRUE`).
...	Additional parameters to be passed to plotting function from `as.dendrogram`. Type `?as.dendrogram` for further information. This option is usually not needed, except if special designs are needed.

Details

align: Aligning will reverse constructs if necessary to yield a maximal similarity between constructs. In a first step the constructs are clustered including both directions. In a second step the direction of a construct that yields smaller distances to the adjacent constructs is preserved and used for the final clustering. As a result, every construct is included once but with an orientation that guarantees optimal clustering. This approach is akin to the procedure used in FOCUS (Jankowicz & Thomas, 1982).

Value

Reordered `repgrid` object.

Author(s)

Mark Heckmann

References

## End(Not run)
```

---

clusterBoot *Multiscale bootstrap cluster analysis.*

Description

p-values are calculated for each branch of the cluster dendrogram to indicate the stability of a specific partition. `clusterBoot` will yield the same clusters as the `cluster` function (i.e. standard hierarchical clustering) with additional p-values. Two kindes of p-values are reported: bootstrap probabilities (BP) and approximately unbiased (AU) probabilities (see Details section for more information).

Usage

```
clusterBoot(x, along = 1, align = TRUE, dmethod = "euclidean",
  cmethod = "ward", p = 2, nboot = 1000, r = seq(0.8, 1.4, by = 0.1),
  seed = NULL, ...)
```

Arguments

`x`	`grid object`
`along`	Along which dimension to cluster. 1 = constructs, 2= elements.
`align`	Whether the constructs should be aligned before clustering (default is `TRUE`). If not, the grid matrix is clustered as is. See Details section for more information.

`dmethod`	The distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given. For additional information on the different types type `?dist`.
`cmethod`	The agglomeration method to be used. This should be (an unambiguous abbreviation of) one of `"ward"`, `"single"`, `"complete"`, `"average"`, `"mcquitty"`, `"median"` or `"centroid"`.
`p`	Power of the Minkowski metric. Not yet passed on to pvclust!
`nboot`	the number of bootstrap replications. The default is `1000`.
`r`	numeric vector which specifies the relative sample sizes of bootstrap replications. For original sample size n and bootstrap sample size n', this is defined as $r = n'/n$.
`seed`	Random seed for bootstrapping. Can be set for reproducibility (see `set.seed`). Usually not needed.
`...`	Arguments to pass on to `pvclust`.

Details

In standard (hierarchical) cluster analysis the question arises which of the idientified structures are significant or just emerged by chance. Over the last decade several methods have been developed to test structures for robustness. One line of research in this area is based on resampling. The idea is to resample the rows or columns of the data matrix and to build the dendrogram for each bootstrap sample (Felsenstein, 1985). The p-values indicates the pecentage of times a specific structure is identified across the bootstrap samples. It was shown that the p-value is biased (Hillis & Bull, 1993; Zharkikh & Li, 1995). In the literature several methods for bias correction have been proposed. In `clusterBoot` a method based on the *multiscale bootstrap* is used to derive corrected (approximately unbiased) p-values (Shimodaira, 2002, 2004). In conventional bootstrap analysis the size of the bootstrap sample is identical to the orginal sample size. Multiscale bootstrap varies the bootstrap sample size in order to infer a correction formula for the biased p-value on the basis of the variation of the results for the different sample sizes (Suzuki & Shimodaira, 2006).

align: Aligning will reverse constructs if necessary to yield a maximal similarity between constructs. In a first step the constructs are clustered including both directions. In a second step the direction of a construct that yields smaller distances to the adjacent constructs is preserved and used for the final clustering. As a result, every construct is included once but with an orientation that guarantees optimal clustering. This approach is akin to the procedure used in FOCUS (Jankowicz & Thomas, 1982).

Value

A pvclust object as returned by the function `pvclust`

constructCor *Calculate correlations between constructs.*

Description

Different types of correlations can be requested: PMC, Kendall tau rank correlation, Spearman rank correlation.

Usage

```
constructCor(x, method = c("pearson", "kendall", "spearman"), trim = 20,
  index = FALSE)
```

Arguments

x	repgrid object.
method	A character string indicating which correlation coefficient is to be computed. One of "pearson" (default), "kendall" or "spearman", can be abbreviated. The default is "pearson".
trim	The number of characters a construct is trimmed to (default is 20). If NA no trimming occurs. Trimming simply saves space when displaying correlation of constructs with long names.
index	Whether to print the number of the construct.

Value

Returns a matrix of construct correlations.

Author(s)

Mark Heckmann

   r
   print(r, digits=5)

   # accessing the correlation matrix
   r[1, 3]
```

---

constructD   *Calculate Somers' d for the constructs.*

Description

Somer'ss d is an assymetric association measure as it depends on which variable is set as dependent and independent. The direction of dependency needs to be specified.

Usage

```
constructD(x, dependent = "columns", trim = 30, index = TRUE)
```

Arguments

`x`	`repgrid` object
`dependent`	A string denoting the direction of dependency in the output table (as d is assymetrical). Possible values are `"columns"` (the default) for setting the columns as dependent, `"rows"` for setting the rows as the dependent variable and `"symmetric"` for the symmetrical Somers' d measure (the mean of the two directional values for code"columns" and `"rows"`).
`trim`	The number of characters a construct is trimmed to (default is `30`). If `NA` no trimming occurs. Trimming simply saves space when displaying correlation of constructs with long names.
`index`	Whether to print the number of the construct (default is `TRUE`).

Value

`matrix` of construct correlations.

Note

Thanks to Marc Schwartz for supplying the code to calculate Somers' d.

   constructD(fbb2003, "c")  # row as dependent
   constructD(fbb2003, "s")  # symmetrical index

   # surpress printing
   d <- constructD(fbb2003, out=0, trim=5)
   d

   # more digits
   constructD(fbb2003, dig=3)

   # add index column, no trimming
   constructD(fbb2003, col.index=TRUE, index=F, trim=NA)
```

```
## End(Not run)
```

---

constructPca *Principal component analysis (PCA) of inter-construct correlations.*

Description

Various methods for rotation and methods for the calculation of the correlations are available. Note that the number of factors has to be specified. For more information on the PCA function itself type `?principal`.

Usage

```
constructPca(x, nfactors = 3, rotate = "varimax", method = "pearson",
  trim = NA)
```

Arguments

`x`	`repgrid` object.
`nfactors`	Number of components to extract (default is `3`).
`rotate`	`"none"`, `"varimax"`, `"promax"` and `"cluster"` are possible rotations (default is `none`).
`method`	A character string indicating which correlation coefficient is to be computed. One of `"pearson"` (default), `"kendall"` or `"spearman"`, can be abbreviated. The default is `"pearson"`.
`trim`	The number of characters a construct is trimmed to (default is `7`). If `NA` no trimming occurs. Trimming simply saves space when displaying correlation of constructs with long names.

Value

Returns an object of class `constructPca`.

Author(s)

Mark Heckmann

References

Fransella, F., Bell, R. & Bannister, D. (2003). *A Manual for Repertory Grid Technique* (2. Ed.). Chichester: John Wiley & Sons.

See Also

To extract the PCA loadings for further processing see `constructPcaLoadings`.

Examples

```
## Not run:

   constructPca(bell2010)

   # data from grid manual by Fransella et al. (2003, p. 87)
   # note that the construct order is different
   constructPca(fbb2003, nfactors=2)

   # no rotation
   constructPca(fbb2003, rotate="none")

   # use a different type of correlation (Spearman)
   constructPca(fbb2003, method="spearman")

   # save output to object
   m <- constructPca(fbb2003, nfactors=2)
   m

   # different printing options
   print(m, digits=5)
   print(m, cutoff=.3)

## End(Not run)
```

`constructPcaLoadings` *Extract loadings from PCA of constructs.*

Description

Extract loadings from PCA of constructs.

Usage

```
constructPcaLoadings(x)
```

Arguments

x	`repgrid` object. This object is returned by the function `constructPca`.

Value

A matrix containing the factor loadings.

Examples

```
p <- constructPca(bell2010)
 l <- constructPcaLoadings(p)
 l[1, ]
 l[, 1]
 l[1,1]
```

`constructRmsCor` *Root mean square (RMS) of inter-construct correlations.*

Description

The RMS is also known as 'quadratic mean' of the inter-construct correlations. The RMS serves as a simplification of the correlation table. It reflects the average relation of one construct to all other constructs. Note that as the correlations are squared during its calculation, the RMS is not affected by the sign of the correlation (cf. Fransella, Bell & Bannister, 2003, p. 86).

Usage

```
constructRmsCor(x, method = "pearson", trim = NA)
```

Arguments

x	`repgrid` object
method	A character string indicating which correlation coefficient is to be computed. One of `"pearson"` (default), `"kendall"` or `"spearman"`, can be abbreviated. The default is `"pearson"`.
trim	The number of characters a construct is trimmed to (default is `NA`). If `NA` no trimming occurs. Trimming simply saves space when displaying correlation of constructs with long names.

Value

`dataframe` of the RMS of inter-construct correlations

Author(s)

Mark Heckmann

`data-feixas2004` *Grid data from Feixas and Saul (2004).*

Description

A desription by the authors: "When Teresa, 22 years old, was seen by the second author (LAS) at the psychological services of the University of Salamanca, she was in the final year of her studies in chemical sciences. Although Teresa proves to be an excellent student, she reveals serious doubts about her self worth. She cries frequently, and has great difficulty in meeting others, even though she has a boyfriend who is extremely supportive. Teresa is anxiously hesitant about accepting a new job which would involve moving to another city 600 Km away from home." (Feixas & Saul, 2004, p. 77).

`distance` *Distance measures (between constructs or elements).*

Description

Various distance measures between elements or constructs are calculated.

Usage

```
distance(x, along = 1, dmethod = "euclidean", p = 2, trim = 20,
  index = TRUE, ...)
```

Arguments

`x`	`repgrid` object.
`along`	Whether to calculate distance for 1 = constructs (default) or for 2= elements.
`dmethod`	The distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given. For additional information on the different types type `?dist`.
`p`	The power of the Minkowski distance, in case `"minkowski"` is used as argument for `dmethod`.
`trim`	The number of characters a construct or element is trimmed to (default is `20`). If `NA` no trimming occurs. Trimming simply saves space when displaying correlation of constructs with long names.
`index`	Whether to print the number of the construct or element in front of the name (default is `TRUE`). This is useful to avoid identical row names, which may cause an error.
`...`	Additional parameters to be passed to function `dist`. Type `dist` for further information.

Value

`matrix` object.

Author(s)

Mark Heckmann

Examples

```
## Not run:

   # between constructs
   distance(bell2010, along=1)
   # between elements
   distance(bell2010, along=2)
```

```
# several distance methods
distance(bell2010, dm="man")         # manhattan distance
distance(bell2010, dm="mink", p=3)   # minkowski metric to the power of 3

# to save the results without printing to the console
d <- distance(bell2010, trim=7)
d

# some more options when printing the distance matrix
print(d, digits=5)
print(d, col.index=FALSE)
print(d, upper=FALSE)

# accessing entries from the matrix
d[1,3]

## End(Not run)
```

`distanceHartmann` *'Hartmann distance' (standardized Slater distances).*

Description

Calculate Hartmann distance

Usage

```
distanceHartmann(x, method = "paper", reps = 10000, prob = NULL,
  progress = TRUE, distributions = FALSE)
```

Arguments

x	`repgrid` object.
method	The method used for distance calculation, on of `"paper"`, `"simulate"`, `"new"`. `"paper"` uses the parameters as given in Hartmann (1992) for caclulation. `"simulate"` (default) simulates a Slater distribution for the caclulation. In a future version the time consuming simulation will be replaced by more accurate parameters for Hartmann distances than used in Hartmann (1992).
reps	Number of random grids to generate sample distribution for Slater distances (default is `10000`). Note that a lot of samples may take a while to calculate.
prob	The probability of each rating value to occur. If `NULL` (default) the distribution is uniform. The number of values must match the length of the rating scale.
progress	Whether to show a progress bar during simulation (default is `TRUE`) (for `method="simulate"`). May be useful when the distribution is estimated on the basis of many quasis.
distributions	Wether to additionally return the values of the simulated distributions (Slater etc.) The default is `FALSE` as it will quickly boost the object size.

Details

Hartmann (1992) showed in a simulation study that Slater distances (see `distanceSlater`) based on random grids, for which Slater coined the expression quasis, have a skewed distribution, a mean and a standard deviation depending on the number of constructs elicited. He suggested a linear transformation (z-transformation) which takes into account the estimated (or expected) mean and the standard deviation of the derived distribution to standardize Slater distance scores across different grid sizes. 'Hartmann distances' represent a more accurate version of 'Slater distances'. Note that Hartmann distances are multiplied by -1. Hence, negative Hartmann values represent dissimilarity, i.e. a big Slater distance.

There are two ways to use this function. Hartmann distances can either be calculated based on the reference values (i.e. means and standard deviations of Slater distance distributions) as given by Hartmann in his paper. The second option is to conduct an instant simulation for the supplied grid size for each calculation. The second option will be more accurate when a big number of quasis is used in the simulation.

It is also possible to return the quantiles of the sample distribution and only the element distances consideres 'significant' according to the quantiles defined.

Value

A matrix containing Hartmann distances.
In the attributes several additional parameters can be found:

`"arguments"` A list of several parameters including `mean` and `sd` of Slater distribution.

`"quantiles"` Quantiles for Slater and Hartmann distance distribition.

`"distributions"` List with values of the simulated distributions.

Calculation

The 'Hartmann distance' is calculated as follows (Hartmann 1992, p. 49).

$$D = -1(\frac{D_{slater} - M_c}{sd_c})$$

Where D_{slater} denotes the Slater distances of the grid, M_c the sample distribution's mean value and sd_c the sample distributions's standard deviation.

distanceNormalized *Standardized inter-element distances' (power transformed Hartmann distances).*

Description

Calculate power-transformed Hartmann distances.

Usage

```
distanceNormalized(x, reps = 1000, prob = NULL, progress = TRUE,
  distributions = TRUE)
```

Arguments

- `x` — `repgrid` object.
- `reps` — Number of random grids to generate to produce sample distribution for Hartmann distances (default is `1000`). Note that a lot of samples may take a while to calculate.
- `prob` — The probability of each rating value to occur. If `NULL` (default) the distribution is uniform. The number of values must match the length of the rating scale.
- `progress` — Whether to show a progress bar during simulation (default is `TRUE`) (for `method="simulate"`). May be useful when the distribution is estimated on the basis of many quasis.
- `distributions` — Wether to additionally return the values of the simulated distributions (Slater etc.) The default is `FALSE` as it will quickly boost the object size.

Details

Hartmann (1992) suggested a transformation of Slater (1977) distances to make them independent from the size of a grid. Hartmann distances are supposed to yield stable cutoff values used to determine 'significance' of inter-element distances. It can be shown that Hartmann distances are still affected by grid parameters like size and the range of the rating scale used (Heckmann, 2012). The function `distanceNormalize` applies a Box-Cox (1964) transformation to the Hartmann distances in order to remove the skew of the Hartmann distance distribution. The normalized values show to have more stable cutoffs (quantiles) and better properties for comparison across grids of different size and scale range.

The function `distanceNormalize` can also return the quantiles of the sample distribution and only the element distances consideres 'significant' according to the quantiles defined.

Value

A matrix containing the standardized distances.
Further data is contained in the object's attributes:

- `"arguments"` — A list of several parameters including `mean` and `sd` of Slater distribution.
- `"quantiles"` — Quantiles for Slater, Hartmann and power transformed distance distribitions.
- `"distributions"` — List with values of the simulated distributions, if `distributions=TRUE`.

Calculations

The 'power tranformed Hartmann distance' are calulated as follows: The simulated Hartmann distribution is added a constant as the Box-Cox transformation can only be applied to positive values. Then a range of values for lambda in the Box-Cox transformation (Box & Cox, 1964) are tried out. The best lambda is the one maximizing the correlation of the quantiles with the standard normal distribution. The lambda value maximizing normality is used to transform Hartmann distances. As the resulting scale of the power transformation depends on lambda, the resulting values are z-transformed to derive a common scaling.

The code for the calculation of the optimal lambda was written by Ioannis Kosmidis.

```

`distanceSlater` *'Slater distances' (standardized Euclidean distances).*

Description

Calculate Slater distance.

Usage

```
distanceSlater(x, trim = 20, index = TRUE)
```

Arguments

`x`	`repgrid` object.
`trim`	The number of characters a construct or element is trimmed to (default is `20`). If `NA` no trimming occurs. Trimming simply saves space when displaying correlation of constructs with long names.
`index`	Whether to print the number of the construct or element in front of the name (default is `TRUE`). This is useful to avoid identical row names, which may cause an error.

Details

The euclidean distance is often used as a measure of similarity between elements (see `distance`. A drawback of this measure is that it depends on the range of the rating scale and the number of constructs used, i. e. on the size of a grid.
An approach to standardize the euclidean distance to make it independent from size and range of ratings and was proposed by Slater (1977, pp. 94). The 'Slater distance' is the Euclidean distance divided by the expected distance. Slater distances bigger than 1 are greater than expected, lesser than 1 are smaller than expected. The minimum value is 0 and values bigger than 2 are rarely found. Slater distances have been be used to compare inter-element distances between different grids, where the grids do not need to have the same constructs or elements. Hartmann (1992) showed that Slater distance is not independent of grid size. Also the distribution of the Slater distances is asymmetric. Hence, the upper and lower limit to infer 'significance' of distance is not symmetric. The practical relevance of Hartmann's findings have been demonstrated by Schoeneich and Klapp (1998). To calculate Hartmann's version of the standardized distances see `distanceHartmann`

Value

A matrix with Slater distances.

Calculation

The Slater distance is calculated as follows. For a derivation see Slater (1977, p.94).
Let matrix D contain the row centered ratings. Then

$$P = D^T D$$

and

$$S = tr(P)$$

The expected 'unit of expected distance' results as

$$U = (2S/(m-1))^{1/2}$$

where m denotes the number of elements of the grid. The standardized Slater distances is the matrix of Euclidean distances E devided by the expected distance U.

$$E/U$$

   print(d, cutoffs=c(.8, 1.2))
```

elementCor *Calculate the correlations between elements.*

Description

Note that simple element correlations as a measure of similarity are flawed as they are not invariant to construct reflection (Mackay, 1992; Bell, 2010). A correlation index invariant to construct reflection is Cohen's rc measure (1969), which can be calculated using the argument `rc=TRUE` which is the default option.

Usage

```
elementCor(x, rc = TRUE, method = "pearson", trim = 20, index = TRUE)
```

Arguments

`x`	`repgrid` object.
`rc`	Use Cohen's rc which is invariant to construct reflection (see desciption above). It is used as the default.
`method`	A character string indicating which correlation coefficient is to be computed. One of `"pearson"` (default), `"kendall"` or `"spearman"`, can be abbreviated. The default is `"pearson"`.
`trim`	The number of characters a construct is trimmed to (default is `20`). If `NA` no trimming occurs. Trimming simply saves space when displaying correlation of constructs with long names.
`index`	Whether to print the number of the construct.

Value

`matrix` of element correlations

   elementCor(mackay1992, rc=FALSE, method="spearman")  # Spearman correlation

   # format output
   elementCor(mackay1992, trim=6)
   elementCor(mackay1992, index=FALSE, trim=6)

   # save as object for further processing
   r <- elementCor(mackay1992)
   r

   # change output of object
   print(r, digits=5)
   print(r, col.index=FALSE)
   print(r, upper=FALSE)

   # accessing elements of the correlation matrix
   r[1,3]
```

`elementRmsCor` *Root mean square (RMS) of inter-element correlations.*

Description

The RMS is also known as 'quadratic mean' of the inter-element correlations. The RMS serves as a simplification of the correlation table. It reflects the average relation of one element with all other elements. Note that as the correlations are squared during its calculation, the RMS is not affected by the sign of the correlation (cf. Fransella, Bell & Bannister, 2003, p. 86).

Usage

```
elementRmsCor(x, rc = TRUE, method = "pearson", trim = NA)
```

Arguments

`x`	`repgrid` object.
`rc`	Whether to use Cohen's rc which is invariant to construct reflection (see desciption above). It is used as the default.
`method`	A character string indicating which correlation coefficient to be computed. One of `"pearson"` (default), `"kendall"` or `"spearman"`, can be abbreviated. The default is `"pearson"`.
`trim`	The number of characters an element is trimmed to (default is `NA`). If `NA` no trimming occurs. Trimming simply saves space when displaying correlation of constructs with long names.

Details

Note that simple element correlations as a measure of similarity are flawed as they are not invariant to construct reflection (Mackay, 1992; Bell, 2010). A correlation index invariant to construct reflection is Cohen's rc measure (1969), which can be calculated using the argument `rc=TRUE` which is the default option in this function.

Value

`dataframe` of the RMS of inter-element correlations

   print(r, digits=5)

   # access second row of calculation results
   r[2, "RMS"]
```

---

home *Rotate the interactive 3D device to default views.*

Description

Rotate the interactive 3D device to a default viewpoint or to a position defined by `theta` and `phi` in Euler angles. Three default viewpoints are implemented rendering a view so that two axes span a plane and the third axis is poiting out of the screen.

Usage

```
home(view = 1, theta = NULL, phi = NULL)
```

Arguments

`view`	Numeric. Specifying one of three default views. 1 = XY, 2=XZ and 3=YZ-plane.
`theta`	Numeric. Euler angle. Overrides view setting.
`phi`	Numeric. Euler angle. Overrides view setting. return `NULL`.

Author(s)

Mark Heckmann

   home(2)
   home(3)
   home(1)
   home(theta=45, phi=45)

## End(Not run)
```

`importExcel` *Import grid data from an Excel file.*

Description

If you do not have a grid program at hand you can define a grid using Microsoft Excel and by saving it as a `.xlsx` or `.xls` file. The `.xlsx` or `.xls` file has to be in specified fixed format. The first row contains the minimum of the rating scale, the names of the elements and the maximum of the rating scale. Below every row contains the left construct pole, the ratings and the right construct pole.

Usage

```
importExcel(file, dir = NULL, sheetIndex = 1, min = NULL, max = NULL)
```

Arguments

`file`	A vector of filenames including the full path if file is not in current working directory. The file suffix has to be `.xlsx` or `.xls`. If no file is supplied a selection pop up menu is opened to select the files.
`dir`	Alternative way to supply the directory where the file is located (default `NULL`).
`sheetIndex`	The number of the Excel sheet that contains the grid data.
`min`	Optional argument (`numeric`, default `NULL`) for minimum rating value in grid.
`max`	Optional argument (`numeric`, default `NULL`) for maximum rating value in grid.

Details

1 & `element 1` & `element 2` & `element 3` & 5
1 & `element 1` & `element 2` & `element 3` & 5
1 & `element 1` & `element 2` & `element 3` & 5

Note that the maximum and minimum value has to be defined using the `min` and `max` arguments if no values are supplied at the beginning and end of the first row. Otherwise the scaling range is inferred from the available data and a warning is issued as the range may be erroneous. This may effect other functions that depend on knowing the correct range and it is thus strongly recommended to set the scale range correctly.

A sample Excel file can be found here: http://www.openrepgrid.uni-bremen.de/data/grid.xlsx.

Value

A single `repgrid` object in case one file and a list of `repgrid` objects in case multiple files are imported.

rg <- importExcel(files)

## End(Not run)
```

---

importGridcor *Import GRIDCOR data files.*

Description

Reads the file format that is used by the grid program GRIDCOR (Feixas & Cornejo, 2002).

Usage

```
importGridcor(file, dir = NULL)
```

Arguments

file	filename including path if file is not in current working directory. File can also be a complete URL. The fileformat is .dat.
dir	alternative way to supply the directory where the file is located (default NULL).

Value

a single repgrid object in case one file and a list of repgrid objects in case multiple files are imported.

Note

Note that the GRIDCOR data sets the minimum ratings scale range to 1. The maximum value can differ and is defined in the data file.

Also note that both Gridcor and Gridstat data files do have the same suffix .dat. Make sure not to mix themn up.

Examples

```
## Not run:

# using the pop-up selection menu
rg <- importGridcor()

# supposing that the data file gridcor.dat is in the current directory
file <- "gridcor.dat"
rg <- importGridcor(file)

# specifying a directory (arbitrary example directory)
dir <- "/Users/markheckmann/data"
rg <- importGridcor(file, dir)

# using a full path
rg <- importGridcor("/Users/markheckmann/data/gridcor.dat")

# load GRIDCOR data from URL
rg <- importGridcor("http://www.openrepgrid.uni-bremen.de/data/gridcor.dat")

## End(Not run)
```

`importGridstat` *Import Gridstat data files.*

Description

Reads the file format that is used by the latest version of the grid program gridstat (Bell, 1998).

Usage

```
importGridstat(file, dir = NULL, min = NULL, max = NULL)
```

Arguments

`file`	Filename including path if file is not in current working directory. File can also be a complete URL. The fileformat is `.dat`. If no file is supplied a selection pop up menu is opened to select the files.

`dir`	Alternative way to supply the directory where the file is located (default `NULL`).
`min`	Optional argument (`numeric`, default `NULL`) for minimum rating value in grid.
`max`	Optional argument (`numeric`, default `NULL`) for maximum rating value in grid.

Value

A single `repgrid` object in case one file and a list of `repgrid` objects in case multiple files are imported.

Note

Note that the gridstat data format does not contain explicit information about the range of the rating scale used (minimum and maximum). By default the range is inferred by scanning the ratings and picking the minimal and maximal values as rating range. You can set the minimal and maximal value by hand using the `min` and `max` arguments or by using the `setScale()` function. Note that if the rating range is not set, it may cause several functions to not work properly. A warning will be issued if the range is not set explicitly when using the importing function.

The function only reads data from the latest GridStat version. The latest version allows the seperation of the left and right pole by using on of the following symbols `/:-` (hyphene, colon and dash). Older versions may not seperate the left and right pole. This will cause all labels to be assigned to the left pole only when importing. You may fix this by simply entering one of the construct seperator symbols into the GridStat file between each left and right construct pole.

The third line of a GridStat file may contain a no labels statement (i.e. a line containing any string of 'NOLA', 'NO L', 'NoLa', 'No L', 'Nola', 'No l', 'nola' or 'no l'). In this case only ratings are supplied, hence, default names are assigned to elements and constructs.

rg <- importGridstat(file, dir, min=1, max=6)

## End(Not run)
```

---

importGridsuite *Import Gridsuite data files.*

Description

Import Gridsuite data files.

Usage

```
importGridsuite(file, dir = NULL)
```

Arguments

file	Filename including path if file is not in current working directory. File can also be a complete URL. The fileformat is .dat.
dir	Alternative way to supply the directory where the file is located (default NULL).

Value

A single repgrid object in case one file and a list of repgrid objects in case multiple files are imported.

Note

The developers of Gridsuite have proposed to use an XML scheme as a standard exchange format for repertory grid data (Walter, Bacher & Fromm, 2004). This approach is also embraced by the OpenRepGrid package.

TODO: The element and construct IDs are not used yet. Thus, if the output should be in different order the current mechanism will cause false assignments.

importScivesco *Import sci:vesco data files.*

Description

Import sci:vesco data files.

Usage

```
importScivesco(file, dir = NULL)
```

Arguments

file	Filename including path if file is not in current working directory. File can also be a complete URL. The fileformat is .dat.
dir	Alternative way to supply the directory where the file is located (default NULL).

Value

A single repgrid object in case one file and a list of repgrid objects in case multiple files are imported.

Note

Sci:Vesco offers the options to rate the construct poles seperately or using a bipolar scale. The seperated rating is done using the "tetralemma" field. The field is a bivariate plane on which each of the four (tetra) corners has a different meaning in terms of rating. Using this approach also allows ratings like: "both poles apply", "none of the poles apply" and all intermediate ratings can be chosen. This relaxes the bipolarity assumption often assumed in grid theory and allows for deviation from a strict bipolar rating if the constructs are not applied in a bipolar way. Using the tetralemma field for rating requires to analyze each construct seperately though. This means we get a double entry grid where the emergent and constrast pole ratings might not simply be a reflection of on another. The tetralemma field is not yet supported and importing will fail. Currently only bipolar ratings are suppoerted.

If a tetralemma field has been used for rating, OpenRepGrid will offer the option to transform the scores into "normal" grid ratings (i.e. restricted to bipolarity) by projecting the ratings from the bivariate tetralemma field onto the diagonal of the tetralemma field and thus forcing a bipolar rating type. This option is not recommended due to the fact that the conversion is susceptible to error when both ratings are near to zero.

TODO: For developers: The element IDs are not used yet. This might cause wrong assignments.

---

importTxt *Import grid data from a text file.*

Description

If you do not have a grid program at hand you can define a grid using a standard text editor and by saving it as a `.txt` file. The `.txt` file has to be in a fixed format. There are three mandatory blocks each starting and ending with a predefined tag in uppercase letters. The first block starts with `ELEMENTS` and ends with `END ELEMENTS` and contains one element in each line. The other mandatory blocks contain the constructs and ratings (see below). In the block containing the constructs the left and right pole are seperated by a colon (:). To define missing values use `NA` like in the example below. One optional block contains the range of the rating scale used defined by two numbers. The order of the blocks is arbitrary. All text not contained within the blocks is discarded and can thus be used for comments.

Usage

```
importTxt(file, dir = NULL, min = NULL, max = NULL)
```

Arguments

`file`	A vector of filenames including the full path if file is not in current working directory. File can also be a complete URL. The file suffix has to be `.txt`. If no file is supplied a selection pop up menu is opened to select the files.
`dir`	Alternative way to supply the directory where the file is located (default `NULL`).
`min`	Optional argument (`numeric`, default `NULL`) for minimum rating value in grid.
`max`	Optional argument (`numeric`, default `NULL`) for maximum rating value in grid.

Details

```
---------------- .txt file -----------------

anything not contained within the tags will be discarded
ELEMENTS
element 1
element 2
element 3
END ELEMENTS
```

```
CONSTRUCTS
left pole 1 : right pole 1
left pole 2 : right pole 2
left pole 3 : right pole 3
left pole 4 : right pole 4
END CONSTRUCTS

RATINGS
1 3 2
4 1 1
1 4 4
3 1 1
END RATINGS

RANGE
1 4
END RANGE
---------------- end of file ----------------
```

Note that the maximum and minimum value has to be defined using the `min` and `max` arguments if no `RANGE` block is contained in the data file. Otherwise the scaling range is inferred from the available data and a warning is issued as the range may be erroneous. This may effect other functions that depend on knowing the correct range and it is thus strongly recommended to set the scale range correctly.

Value

A single `repgrid` object in case one file and a list of `repgrid` objects in case multiple files are imported.

indexBias *Calculate 'bias' of grid as defined by Slater (1977).*

Description

"Bias records a tendency for reponses to accumulate at one end of the grading scale" (Slater, 1977, p.88).

Usage

```
indexBias(x, min, max, digits = 2)
```

Arguments

x	repgrid object.
min	Minimum grid scale value.
max	Maximum grid scale value.
digits	Numeric. Number of digits to round to (default is 2).

Value

Numeric.

Note

STATUS: Working and checked against example in Slater, 1977, p. 87.

`indexConflict1` *Conflict measure for grids (Slade & Sheehan, 1979) based on correlations.*

Description

Conflict measure as proposed by Slade and Sheehan (1979)

Usage

```
indexConflict1(x)
```

Arguments

x	`repgrid` object.

Details

The first approach to mathematically derive a conflict measure based on grid data was presented by Slade and Sheehan (1979). Their operationalization is based on an approach by Lauterbach (1975) who applied the *balance theory* (Heider, 1958) for a quantitative assessment of psychological conflict. It is based on a count of balanced and imbalanced triads of construct correlations. A triad is imbalanced if one or all three of the correlations are negative, i. e. leading to contrary implications. This approach was shown by Winter (1982) to be flawed. An improved version was proposed by Bassler et al. (1992) and has been implemented in the function `indexConflict2`.

The table below shows when a triad made up of the constructs A, B, and C is balanced and imbalanced.

cor(A,B)	cor(A,C)	cor(B,C)	Triad characteristic
+	+	+	balanced
+	+	-	imbalanced
+	-	+	imbalanced
+	-	-	balanced
-	+	+	imbalanced
-	+	-	balanced
-	-	+	balanced
-	-	-	imbalanced

Value

A list with the following elements:

- `total` Total number of triads
- `imbalanced` Number of imbalanced triads
- `prop.balanced` Proportion of balanced triads
- `prop.imbalanced` Proportion of imbalanced triads

## End(Not run)
```

`indexConflict2` *Conflict measure for grids (Bassler et al., 1992) based on correlations.*

Description

Conflict measure as proposed by Bassler et al. (1992).

Usage

```
indexConflict2(x, crit = 0.03)
```

Arguments

`x`	`repgrid` object.
`crit`	Sensitivity criterion with which triads are marked as unbalanced. A bigger values willl lead to less imbalanced triads. The default is `0.03`. The value should be adjusted with regard to the researchers interest.

Details

The function calculates the conflict measure as devised by Bassler et al. (1992). It is an improved version of the ideas by Slade and Sheehan (1979) that have been implemented in the function `indexConflict1`. The new approach also takes into account the magnitude of the correlations in a traid to assess whether it is balanced or imbalanced. As a result, small correlations that are psychologically meaningless are considered accordingly. Also, correlations with a small magnitude, i. e. near zero, which may be positive or negative due to chance alone will no longer distort the measure (Bassler et al., 1992).

Description of the balance / imbalance assessment:

1. Order correlations of the triad by absolute magnitude, so that $r_{max} > r_{mdn} > r_{min}$.
2. Apply Fisher's Z-transformation and devision by 3 to yield values between 1 and -1
3. Check whether the triad is balanced by assessing if the following relation holds:
   - If $Z_{max} Z_{mdn} > 0$, the triad is balanced if $Z_{max} Z_{mdn} - Z_{min} <= crit$ Z_max x Z_mdn - Z_min <= crit .
   - If $Z_{max} Z_{mdn} < 0$, the triad is balanced if $Z_{min} - Z_{max} Z_{mdn} <= crit$ Z_min - Z_max x Z_mdn <= crit .

Personal remarks (MH)

I am a bit suspicious about step 2 from above. To devide by 3 appears pretty arbitrary. The r for a z-values of 3 is 0.9950548 and not 1. The r for 4 is 0.9993293. Hence, why not a value of 4, 5, or 6? Denoting the value to devide by with `a`, the relation for the first case translates into $aZ_{max} Z_{mdn} <= \frac{crit}{a} + Z_{min}$ a x Z_max x Z_mdn =< crit/a + Z_min. This shows that a bigger value of `a` will make it more improbabale that the relation will hold.

`indexConflict3` *Conflict or inconsistenciy measure for grids (Bell, 2004) based on distances.*

Description

Conflict measure as proposed by Bell (2004).

Usage

```
indexConflict3(x, p = 2, e.out = NA, e.threshold = NA, c.out = NA,
  c.threshold = NA, trim = 20)
```

Arguments

`x`	`repgrid` object.
`p`	The power of the Minkowski distance. `p=2` (default) will result in euclidean distances, `p=1` in city block distances.
`e.out`	Numeric. A vector giving the indexes of the elements for which detailed stats (number of conflicts per element, discrepancies for triangles etc.) are promted (default `NA`, i.e. no detailed stats for any element).
`e.threshold`	Numeric. Detailed stats are prompted for those elements with a an attributable percentage to the overall conflicts higher than the supplied threshold (default `NA`).
`c.out`	Numeric. A vector giving the indexes of the constructs for which detailed stats (discrepancies for triangles etc.) are promted (default `NA`, i. e. no detailed stats).
`c.threshold`	Numeric. Detailed stats are prompted for those constructs with a an attributable percentage to the overall conflicts higher than the supplied threshold (default `NA`).
`trim`	The number of characters a construct (element) is trimmed to (default is `10`). If `NA` no trimming is done. Trimming simply saves space when displaying the output.

Details

Measure of conflict or inconsistency as proposed by Bell (2004). The identification of conflict is based on distances rather than correlations as in other measures of conflict `indexConflict1` and `indexConflict2`. It assesses if the distances between all components of a triad, made up of one element and two constructs, satisfies the "triangle inequality" (cf. Bell, 2004). If not, a triad is regarded as conflictive. An advantage of the measure is that it can be interpreted not only as a global measure for a grid but also on an element, construct, and element by construct level making it valuable for detailed feedback. Also, differences in conflict can be submitted to statistical testing procedures.

Status: working; output for euclidean and manhattan distance checked against Gridstat output.
TODO: standardization and z-test for discrepancies; Index of Conflict Variation.

Value

A list (invisibly) containing containing:

`potential`	number of potential conflicts
`actual`	count of actual conflicts
`overall`	percentage of conflictive relations
`e.count`	number of involvements of each element in conflictive relations
`e.perc`	percentage of involvement of each element in total of conflictive relations
`e.count`	number of involvements of each construct in conflictive relation
`c.perc`	percentage of involvement of each construct in total of conflictive relations
`e.stats`	detailed statistics for prompted elements

c.stats	detailed statistics for prompted constructs
e.threshold	threshold percentage. Used by print method
c.threshold	threshold percentage. Used by print method
enames	trimmed element names. Used by print method
cnames	trimmed construct names. Used by print method

output

For further control over the output see print.indexConflict3.

## End(Not run)
```

indexDilemma *Detect implicative dilemmas (conflicts).*

Description

Implicative Dilemmas

Usage

```
indexDilemma(x, self, ideal, diff.mode = 1, diff.congruent = NA,
  diff.discrepant = NA, diff.poles = 1, r.min = 0.35, exclude = FALSE,
  digits = 2, show = F, output = 1, index = T, trim = 20)
```

Arguments

x	repgrid object.
self	Numeric. Index of self element.
ideal	Numeric. Index of ideal self element.
diff.mode	Numeric. Mode to classify construct pairs into congruent and discrepant. diff.mode=1 will use the difference in ratings between the self and the ideal element to determine if the construct is congruent or discrepant. No other modes have yet been implemented.
diff.congruent	Is used if diff.mode=1. Maximal difference between element ratings to define construct as congruent (default diff.congruent=1). Note that the value needs to be adjusted by the user according to the rating scale used.
diff.discrepant	Is used if diff.mode=1. Minimal difference between element ratings to define construct as discrepant (default diff.discrepant=3). Note that the value needs to be adjusted by the user according to the rating scale used.
diff.poles	Not yet implemented.
r.min	Minimal correlation to determine implications between constructs.
exclude	Whether to exclude the elements self and ideal self during the calculation of the inter-construct correlations. (default is FALSE).
digits	Numeric. Number of digits to round to (default is 2).
show	Whether to additionally plot the distribution of correlations to help the user assess what level is adequate for r.min.
output	The type of output printed to the console. output=1 prints classification of the construct into congruent and discrepant and the detected dilemmas. output=1 only prints the latter. output=0 will surpress printing. Note that the type of output does not affect the object that is returned invisibly which will be the same in any case (see value).
index	Whether to print index numbers in front of each construct (default is TRUE).
trim	The number of characters a construct (element) is trimmed to (default is 20). If NA no trimming is done. Trimming simply saves space when displaying the output.

Details

Implicative dilemmas are closely related to the notion of conflict. An implicative dilemma arises when a desired change on one construct is associated with an undesired implication on another construct. E. g. a timid subject may want to become more socially skilled but associates being socially skilled with different negative characteristics (selfish, insensitive etc.). Hence, he may anticipate that becoming less timid will also make him more selfish (cf. Winter, 1982). As a consequence the subject will resist to the change if the negative presumed implications will threaten the patients identity and the predictive power of his construct system. From this stance the resistance to change is a logical consequence coherent with the subjects construct system (Feixas, Saul, & Sanchez, 2000). The investigation of the role of cognitive dilemma in different disorders in the context of PCP is a current field of research (e.g. Feixas & Saul, 2004, Dorough et al. 2007).

The detection of implicative dilemmas happens in two steps. First the constructs are classified as being 'congruent' or 'discrepant'. Second the correlation between a congruent and discrepant construct pair is assessed if it is big enough to indicate an implication.

Classifying the construct
To detect implicit dilemmas the construct pairs are first identified as 'congruent' or 'discrepant'. The assessment is based on the rating differences between the elements 'self' and 'ideal self'. A construct is 'congruent' if the construction of the 'self' and the preferred state (i.e. ideal self) are the same or similar. A construct is discrepant if the construction of the 'self' and the 'ideal' is dissimilar. Suppose the element 'self' is rated 2 and 'ideal self' 5 on a scale from 1 to 6. The ratings differences are 5-2 = 3. If this difference is smaller than e.g. 1 the construct is 'congruent', if it is bigger than 3 it is 'discrepant'.

The values used to classify the constructs 'congruent' or 'discrepant' can be determined in several ways (cf. Bell, 2009):

1. They are set 'a priori'.
2. They are implicitly derived by taking into account the rating differences to the other constructs. Not yet implemented.

The value mode is determined via the argument `diff.mode`.
If no 'a priori' criteria to determine if the construct is congruent or discrepant is supplied as an argument, the values are chosen acording to the range of the rating scale used. For the following scales the defaults are chosen as:

Scale	'A priori' criteria
1 2	–> con: <=0 disc: >=1
1 2 3	–> con: <=0 disc: >=2
1 2 3 4	–> con: <=0 disc: >=2
1 2 3 4 5	–> con: <=1 disc: >=3
1 2 3 4 5 6	–> con: <=1 disc: >=3
1 2 3 4 5 6 7	–> con: <=1 disc: >=4
1 2 3 4 5 6 7 8	–> con: <=1 disc: >=5
1 2 3 4 5 6 7 8 9	–> con: <=2 disc: >=5
1 2 3 4 5 6 7 8 9 10	–> con: <=2 disc: >=6

Defining the correlations
As the implications between constructs cannot be derived from a rating grid directly, the correlation between two constructs is used as an indicator for implication. A large correlation means that one construct pole implies the other. A small correlation indicates a lack of implication. The minimum criterion for a correlation to indicate implication is set to .35 (cf. Feixas & Saul, 2004). The user may also chose another value. To get a an impression of the distribution of correlations in the grid, a visualization can be prompted via the argument `show`. When calculating the correlation used to assess if an implication is given or not, the elements under consideration (i. e. self and ideal self) can be included (default) or excluded. The options will cause different correlations (see argument `exclude`).

Example of an implicative dilemma
A depressive person considers herself as timid and wished to change to the opposite pole she defines as extraverted. This construct is called discrepant as the construction of the 'self' and the desired state (e.g. described by the 'ideal self') on this construct differ. The person also considers herself as sensitive (preferred pole) for which the opposite pole is selfish. This construct is congruent, as the person construes herself as she would like to be. If the person now changed on the discrepant construct from the undesired to the desired pole, i.e. from timid to extraverted, the question can be asked what consequences such a change has. If the person construes being timid and being sensitive as related and that someone who is extraverted will not be timid, a change on the first construct will imply a change on the congruent construct as well. Hence, the positive shift from timid to extraverted is presumed to have a undesired effect in moving from sensitive towards selflish. This relation is called an implicative dilemma. As the implications of change on a construct cannot be derived from a rating grid directly, the correlation between two constructs is used as an indicator for implication.

Value

Called for console output. Invisbly returns a list containing the result dataframes and all results from the calculations.

`indexIntensity` *Intensity index*

Description

Calculate intensity index.

Usage

```
indexIntensity(x, rc = FALSE, trim = 30)
```

Arguments

x	`repgrid` object.
rc	Whether to use Cohen's rc for the calculation of inter-element correlations. See `elementCor` for further explanations of this measure.
trim	The number of characters a construct is trimmed to (default is `30`). If `NA` no trimming occurs. Trimming simply saves space when displaying correlation of constructs or elements with long names.

Details

The Intensity index has been suggested by Bannister (1960) as a measure of the amount of construct linkage. Bannister suggested that the score reflects the degree of organization of the construct system under investigation (Bannister & Mair, 1968). The index resulted from his and his colleagues work on construction systems of patient suffering schizophrenic thought disorder. The concept of intensity has a theoretical connection to the notion of "tight" and "loose" construing as proposed by Kelly (1991). While tight constructs lead to unvarying prediction, loose constructs allow for varying predictions. Bannister hypothesized that schizophrenic thought disorder is liked to a process of extremely loose construing leading to a loss of predictive power of the subject's construct system. The Intensity score as a structural measure is thought to reflect this type of system disintegration (Bannister, 1960).

Implementation as in the Gridcor programme and explained on the correspoding help pages: "...the sum of the squared values of the correlations of each construct with the rest of the constructs, averaged by the total number of constructs minus one. This process is repeated with each element, and the overall Intensity is calculated by averaging the intensity scores of constructs and elements." `http://www.terapiacognitiva.net/record/pag/man11.htm`. Currently the total is calculated as the unweighted average of all single scores (for elements and construct).

Value

An object of class `indexIntensity` containing a list with the following elements:

`c.int`	Intensity scores by construct.
`e.int`	Intensity scores by element.
`c.int.mean`	Average intensity score for constructs.
`e.int.mean`	Average intensity score for elements.
`total.int`	Total intensity score.

`indexPvaff` *Percentage of Variance Accounted for by the First Factor (PVAFF)*

Description

The PVAFF is used as a measure of cognitive complexity. It was introduced in an unpublished PhD thesis by Jones (1954, cit. Bonarius, 1965). To calculate it, the 'first factor' is extracted from the construct correlation matrix by principal component analysis. The PVAFF reflects the amount of variation that is accounted for by a single linear component. If a single latent component is able to explain the variation in the grid, the cognitive complexity is said to be low. In this case the construct system is regarded as 'simple' (Bell, 2003).

Usage

```
indexPvaff(x)
```

Arguments

`x`	`repgrid` object.

Details

The percentage of variance is calculated using the corelation matrix of te constructs submitted to `svd`.

Development

TODO: Results have not yet been checked against other grid programs.

```

`indexVariability` *Calculate 'variability' of a grid as defined by Slater (1977).*

Description

Variability records a tendency for the responses to gravitate towards both end of the gradings scale. (Slater, 1977, p.88).

Usage

```
indexVariability(x, min, max, digits = 2)
```

Arguments

`x`	`repgrid` object.
`min`	Minimum grid scale value.
`max`	Maximum grdi scale value.
`digits`	Numeric. Number of digits to round to (default is 2).

Value

Numeric.

Note

left *Move construct or element in grid to the left, right, up or down.*

Description

Move construct or element in grid to the left, right, up or down.

Move element in grid to the right.

Move construct in grid upwards.

Move construct in grid downwards.

Usage

```
left(x, pos = 0)

right(x, pos = 0)

up(x, pos = 0)

down(x, pos = 0)
```

Arguments

x	`repgrid` object.
pos	Row (column) number of construct (element) to be moved leftwards, rightwards, upwards or downwards. The default is `0`. For indexes outside the range of the grid no moving is done.

Value

`repgrid` object.

`repgrid` object

`repgrid` object

`repgrid` object

Author(s)

Mark Heckmann

Examples

```
## Not run:
   x <- randomGrid()
   left(x, 2)    # 2nd element to the left
   right(x, 1)   # 1st element to the right
   up(x, 2)      # 2nd construct upwards
   down(x, 1)    # 1st construct downwards

## End(Not run)
```

---

makeRepgrid *Make a new repgrid object.*

Description

The function creates a `repgrid` object from scratch. A number of paramters have to be defined in order to make a new grid (see parameters).

Usage

```
makeRepgrid(args)
```

Arguments

`args`	Arguments needed for the construction of the grid (list). These include `name` followed by a vector containing the element names. `l.name` followed by a vector with the left construct poles. `r.name` followed by a vector with the right construct poles. `scores` followed by a vector containing the rating scores row wise.

Value

NULL

Author(s)

Mark Heckmann

Examples

```
## Not run:

   # make list object containing the arguments
   args <- list( name=c("element_1", "element_2", "element_3", "element_4"),
              l.name=c("left_1", "left_2", "left_3"),
             r.name=c("right_1", "right_2", "right_3"),
             scores=c( 1,0,1,0,
                1,1,1,0,
                1,0,1,0 ) )
   # make grid object
   x <- makeRepgrid(args)
   x

## End(Not run)
```

`normalize` *Normalize rows or columns by its standard deviation.*

Description

Normalize rows or columns by its standard deviation.

Usage

```
normalize(x, normalize = 0, ...)
```

Arguments

`x`	`matrix`
`normalize`	A numeric value indicating along what direction (rows, columns) to normalize by standard deviations. `0 = none, 1= rows, 2 = columns` (default is `0`).
`...`	Not evaluated.

Value

Not yet definde TODO!

Author(s)

Mark Heckmann

Examples

```
## Not run:

 x <- matrix(sample(1:5, 20, rep=T), 4)
 normalize(x, 1)       # normalizing rows
 normalize(x, 2)       # normalizing columns

## End(Not run)
```

`OpenRepGrid` **OpenRepGrid**: *an R package for the analysis of repertory grids.*

Description

The **OpenRepGrid** package provides tools for the analysis of repertory grid data. The repertory grid is a method devised by George Alexander Kelly in his seminal work "The Psychology of Personal Constructs" published in 1955. The repertory grid has been used in and outside the context of Personal Construct Psychology (PCP) in a broad range of fields. For an introduction into the technique see e.g. Fransella, Bell and Bannister (2003).

Note

To get started with **OpenRepGrid** visit the project's home under `www.openrepgrid.org`. On this site you will find tutorials, explanation about the theory, methods of analysis and the according R code.

To see the preferable citation of the **OpenRepGrid** package, type `citation("OpenRepGrid")` into the R console.

Disclaimer: Note that the package is distributed under the GPL 2 license. It is work in progress and is continuously being improved by hopefully numerous contributors. It may contain bugs and errors. There is no warranty whatsoever for the program.

Author(s)

Current members of the **OpenRepGrid** development team: Mark Heckmann. Everyone who is interested in developing the package is invited to join.

The **OpenRepGrid** package development is hosted on github (`http://github.com/markheckmann/OpenRepGrid`). The github site provides information and allows to file bug reports or feature requests. Bug reports can also be emailed to the package maintainer or issued on `http://www.openrepgrid.org` under section *Suggestions/Issues*. The package maintainer is Mark Heckmann <heckmann(at)uni-bremen.de>.

OpenRepGrid-overview **OpenRepGrid**: *Annotated overview of package functions.*

Description

This documentation page contains an overview over the package functions ordered by topics. The best place to start learning OpenRepGrid will be the package website http://www.openrepgrid.org though.

Functions sorted by topic

Manipulating grids

left	Move construct(s) to the left
right	Move construct(s) to the right
up	Move construct(s) upwards
down	Move construct(s) downwards

Loading and saving data

importGridcor	Import GRIDCOR data files
importGridstat	Import Gridstat data files
importGridsuite	Import Gridsuite data files
importScivesco	Import sci:vesco data files
importTxt	Import grid data from a text file
saveAsTxt	Save grid in a text file (txt)

Analyzing constructs

Descriptive statistics of constructs Construct correlations distance Root mean square of inter-construct correlations Somers' D Principal component analysis (PCA) of construct correlation matrix Cluster analysis of constructs

Analyzing elements

Visual representation

Bertin plots

bertin	Make Bertin display of grid data

bertinCluster	Bertin display with corresponding cluster anaylsis

Biplots

biplot2d	Draw a two-dimensional biplot
biplotEsa2d	Plot an eigenstructure analysis (ESA) biplot in 2D
biplotSlater2d	Draws Slater's INGRID biplot in 2D
biplotPseudo3d	See 'biplotPseudo3d' for its use. Draws a biplot of the grid in 2D with depth impression (pseudo 3
biplotEsaPseudo3d	Plot an eigenstructure analysis (ESA) in 2D grid with 3D impression (pseudo 3D)
biplotSlaterPseudo3d	Draws Slater's biplot in 2D with depth impression (pseudo 3D)
biplot3d	Draw grid in rgl (3D device)
biplotEsa3d	Draw the eigenstructure analysis (ESA) biplot in rgl (3D device)
biplotSlater3d	Draw the Slater's INGRID biplot in rgl (3D device)
biplotSimple	A graphically unsophisticated version of a biplot

Index measures

indexConflict1	Conflict measure for grids (Slade & Sheehan, 1979) based on correlations
indexConflict2	Conflict measure for grids (Bassler et al., 1992) based on correlations
indexConflict3	Conflict or inconsistenciy measure for grids (Bell, 2004) based on distances
indexDilemma	Detect implicative dilemmas (conflicts)
indexIntensity	Intensity index
indexPvaff	Percentage of Variance Accounted for by the First Factor (PVAFF)
indexBias	Calculate 'bias' of grid as defined by Slater (1977)
indexVariability	Calculate 'variability' of a grid as defined by Slater (1977)

Special features

alignByIdeal	Align constructs using the ideal element to gain pole preferences
alignByLoadings	Align constructs by loadings on first pricipal component
reorder2d	Order grid by angles between construct and/or elements in 2D

Settings

OpenRepGrid uses several default settings e.g. to determine how many construct characters to display by default when displaying a grid. The function `settings` can be used to show and change these settings. Also it is possible to store the settings to a file and load the settings file to restore the settings.

settings	Show and modify global settings for OpenRepGrid
settingsSave	Save OpenRepGrid settings to file
settingsLoad	Load OpenRepGrid settings from file

Grid datasets

OpenRepGrid already contains some ready to use grid data sets. Most of the datasets are taken from the literature. To output the data simply type Type the name of the dataset to the console and press enter.

Single grids

bell2010	Grid data from a study by Haritos et al. (2004) on role titles; used for demonstration of construct
bellmcgorry1992	Grid from a psychotic patient used in Bell (1997, p. 6). Data originated from a study by Bell and
boeker	Grid from seventeen year old female schizophrenic patient undergoing last stage of psychoanalyt
fbb2003	Dataset used in *A manual for Repertory Grid Technique* (Fransella, Bell, & Bannister, 2003b, p. 6
feixas2004	Grid from a 22 year old Spanish girl suffering self-worth problems (Feixas & Saul, 2004, p. 77).
mackay1992	Dataset *Grid C* used in Mackay's paper on inter-element correlation (1992, p. 65).
leach2001a, leach2001b	Pre- (a) and post-therapy (b) dataset from sexual child abuse survivor (Leach, Freshwater, Aldrid
raeithel	Grid data to demonstrate the use of Bertin diagrams (Raeithel, 1998, p. 223). The context of its a
slater1977a	Drug addict grid dataset from (Slater, 1977, p. 32).
slater1977b	Grid dataset (ranked) from a seventeen year old female psychiatric patient (Slater, 1977, p. 110) s

Multiple grids

Functions for developers

OpenRepGrid: internal functions overview for developers.

Below you find a guide for developers: these functions are usually not needed by the casual user. The internal functions have a twofold goal 1) to provide means for advanced numerical grid analysis and 2) to facilitate function development. The function for these purposes are internal, i.e. they are not visible in the package documentation. Nonetheless they do have a documentation that can be accesses in the same way as for other functions. More in the details section.

Functions for advanced grid analysis

The package provides functions to facilitate numerical research for grids. These comprise the generation of random data, permutation of grids etc. to facilitate Monte Carlo simulations, batch analysis of grids and other methods. With R as an underlying framework, the results of grid analysis easily lend themselves to further statistical processing and analysis within R. This is one of the central advantages for researchers compared to other standard grid software. The following table lists several functions for these purposes.

randomGrid
randomGrids
permuteConstructs
permuteGrid
quasiDistributionDistanceSlater

Modules for function development

Beside the advanced analysis feature the developer's functions comprise low-level modules to create new functions for grid analysis. Though the internal structure of a repgrid object in R is simple (type e.g. `str(bell2010, 2)` to get an impression), it is convenient to not have to deal with access on this level. Several function like e.g. `getElementNames` are convenient wrappers that perform standard tasks needed when implementing new functions. The following table lists several functions for these purposes.

getRatingLayer	Retrieve grid scores from grid object.
getNoOfConstructs	Get the number of constructs in a grid object.
getNoOfElements	Get the number of elements in a grid object.
dim	Get grid dimensions, i.e. contructs x elements.
getScale	Get minimum and maximum scale value used in grid.
getScaleMidpoint	Get midpoint of the grid rating scale.
getConstructNames	Get construct names.
getConstructNames2	Get construct names (another newer version).
getElementNames	Retrieve element names of repgrid object.
bindConstructs	Concatenate the constructs of two grids.
doubleEntry	Join the constructs of a grid with the same reversed constructs.

Other internal functions

importTxtInternal

Author(s)

Current members of the **OpenRepGrid** development team: Mark Heckmann. Everyone who is interested in developing the package is invited to join.

The **OpenRepGrid** package development is hosted on github (http://github.com/markheckmann/OpenRepGrid). The github site provides information and allows to file bug reports or feature requests. Bug reports can also be emailed to the package maintainer or issued on http://www.openrepgrid.org under section *Suggestions/Issues*. The package maintainer is Mark Heckmann <heckmann(at)uni-bremen.de>.

`permuteConstructs` *Generate a list with all possible construct reflections of a grid.*

Description

Generate a list with all possible construct reflections of a grid.

Usage

```
permuteConstructs(x, progress = TRUE)
```

Arguments

`x`	`repgrid` object.
`progress`	Whether to show a progress bar (default is `TRUE`). This may be sensible for a larger number of elements.

Value

A list of `repgrid` objects with all possible permutations of the grid.

Author(s)

Mark Heckmann

Examples

```
## Not run:

  l <- permuteConstructs(mackay1992)
  l

## End(Not run)
```

`randomGrid` *Generate a random grid (quasis) of prompted size.*

Description

This feature is useful for research purposes like exploring distributions of indexes etc.

Usage

```
randomGrid(nc = 10, ne = 15, nwc = 8, nwe = 5, range = c(1, 5),
  prob = NULL, options = 1)
```

Arguments

`nc`	Number of constructs (default 10).
`ne`	Number of elements (default 15).
`nwc`	Number of random words per construct.
`nwe`	Number of random words per element.
`range`	Minimal and maximal scale value (default `c(1, 5)`).
`prob`	The probability of each rating value to occur. If `NULL` (default) the distribution is uniform.
`options`	Use random sentences as constructs and elements (1) or not (0). If not, the elements and constructs are given default names and are numbered.

Value

`repgrid` object.

Author(s)

Mark Heckmann

Examples

```
## Not run:

     x <- randomGrid()
     x
     x <- randomGrid(10, 25)
     x
     x <- randomGrid(10, 25, options=0)
     x

## End(Not run)
```

---

randomGrids *Generate a list of random grids (quasis) of prompted size.*

Description

This feature is useful for research purposes like exploring distributions of indexes etc. The function is a simple wrapper around `randomGrid`.

Usage

```
randomGrids(rep = 3, nc = 10, ne = 15, nwc = 8, nwe = 5,
  range = c(1, 5), prob = NULL, options = 1)
```

Arguments

rep	Number of grids to be produced (default is 3).
nc	Number of constructs (default 10).
ne	Number of elements (default 15).
nwc	Number of random words per construct.
nwe	Number of random words per element.
range	Minimal and maximal scale value (default `c(1, 5)`).
prob	The probability of each rating value to occur. If `NULL` (default) the distribution is uniform.
options	Use random sentences as constructs and elements (1) or not (0). If not, the elements and constructs are given default names and are numbered.

Value

A list of `repgrid` objects.

Author(s)

Mark Heckmann

Examples

```
## Not run:

     x <- randomGrids()
     x
     x <- randomGrids(5, 3, 3)
     x
     x <- randomGrids(5, 3, 3, options=0)
     x

## End(Not run)
```

`reorder2d` *Order grid by angles between construct and/or elements in 2D.*

Description

The approach is to reorder the grid matrix by their polar angles on the first two principal components from a data reduction technique (here the biplot, i.e. SVD). The function `reorder2d` reorders the grid according to the angles between the x-axis and the element (construct) vectors derived from a 2D biplot solution. This approach is apt to identify circumplex structures in data indicated by the diagonal stripe in the display (see examples).

Usage

```
reorder2d(x, dim = c(1, 2), center = 1, normalize = 0, g = 0, h = 1 -
  g, rc = TRUE, re = TRUE, ...)
```

Arguments

x	repgrid object.
dim	Dimension of 2D solution used to calculate angles (default c(1,2)).
center	Numeric. The type of centering to be performed. 0= no centering, 1= row mean centering (construct), 2= column mean centering (elements), 3= double-centering (construct and element means), 4= midpoint centering of rows (constructs). The default is 1 (row centering).
normalize	A numeric value indicating along what direction (rows, columns) to normalize by standard deviations. 0 = none, 1= rows, 2 = columns (default is 0).
g	Power of the singular value matrix assigned to the left singular vectors, i.e. the constructs.
h	Power of the singular value matrix assigned to the right singular vectors, i.e. the elements.
rc	Logical. Reorder constructs by similarity (default TRUE).
re	Logical. Reorder elements by similarity (default TRUE).
...	Not evaluated.

Value

Reordered repgrid object.

Author(s)

Mark Heckmann

Examples

```
## Not run:

   x <- feixas2004
   reorder2d(x)            # reorder grid by angles in first two dimensions
   reorder2d(x, rc=F)      # reorder elements only
   reorder2d(x, re=F)      # reorder constructs only

## End(Not run)
```

`saveAsTxt` *Save grid in a text file (txt).*

Description

`saveAsTxt` will save the grid as a `.txt` file in format used by **OpenRepGrid**. This file format can also easily be edited by hand (see `importTxt` for a description). The funtion will open an interactive dialog box to let the user enter a filename if no `file` argument is supplied in the function call.

Usage

```
saveAsTxt(x, file = NA)
```

Arguments

`x`	`repgrid` object.
`file`	Filename to save the grid to. The name should have the suffix .txt. If the function is called without specifying this argumnet a dialog box is opened.

Value

Invisibly returns the name of the file.

Note

Structure of a txt file that can be read by `importTxt`.

```
---------------- .txt file -----------------

anything not contained within the tags will be discarded

                        ELEMENTS
                        element 1
                        element 2
                        element 3
                        END ELEMENTS

                        CONSTRUCTS
                        left pole 1 : right pole 1
                        left pole 2 : right pole 2
                        left pole 3 : right pole 3
                        left pole 4 : right pole 4
                        END CONSTRUCTS

                        RATINGS
                        1 3 2
                        4 1 1
                        1 4 4
                        3 1 1
```

```
                              END RATINGS

                              RANGE
                              1 4
                              END RANGE

    ---------------- end of file ----------------
```

importTxt

Examples

```
## Not run:

 x <- randomGrid()
 saveToTxt(x, "random.txt")

## End(Not run)
```

`setConstructAttr` *Set the attributes of a construct*

Description

Set the attributes of a construct i.e. name, abbreviation, status etc.

Usage

```
setConstructAttr(x, pos, l.name, r.name, l.preferred, r.preferred, l.emerged,
  r.emerged)
```

Arguments

`x`	`repgrid` object.
`pos`	Row number of construct in the grid to be changed
`l.name`	Name of the left pole (string) (optional).
`r.name`	Name of the right pole (string) (optional).
`l.preferred`	Logical. Is the left one the preferred pole? (optional).
`r.preferred`	Logical. Is the right one the preferred pole? (optional).
`l.emerged`	Logical. Is the left one the emergent pole? (optional).
`r.emerged`	Logical. Is the right one the emergent pole? (optional).

Value

`repgrid` object

Author(s)

Mark Heckmann

See Also

`setElementAttr`

Examples

```
## Not run:

   x <- setConstructAttr(bell2010, 1,
                "new left pole", "new right pole")
   x

## End(Not run)
```

---

setElementAttr *Set the attributes of an element*

Description

Set the attributes of an element i.e. name, abbreviation, status etc.

Usage

```
setElementAttr(x, pos, name, abb, status)
```

Arguments

x	`repgrid` object.
pos	Column number of element in the grid whose attributes are changed.
name	New element name (optional).
abb	Abbreviation of element name (optional).
status	Status of element (e.g. ideal etc.) (optional).

Value

`repgrid` object

Note

Currently the main purpose is to change element names. Future implementations will allow to set further attributes.

Author(s)

Mark Heckmann

See Also

setConstructAttr

Examples

```
## Not run:

   x <- setElementAttr(boeker, 1, "new name")   # change name of first element
   x

## End(Not run)
```

---

setScale — *Set the scale range of a grid.*

Description

The scale must be known for certain operations, e.g. to swap the construct poles. If the user construes a grid he should make sure that the scale range is set correctly.

Usage

```
setScale(x, min, max, step, ...)
```

Arguments

x	repgrid object.
min	Minimal possible scale value for ratings.
max	Maximal possible scale value for ratings.
step	Steps the scales uses (not yet in use).
...	Not evaluated.

Value

repgrid object

Author(s)

Mark Heckmann

Examples

```
## Not run:

   x <- bell2010
   x <- setScale(x, 0, 8)   # not set correctly
   x
   x <- setScale(x, 1, 7)   # set correctly
   x

## End(Not run)
```

`settings` *global settings for OpenRepGrid*

Description

global settings for OpenRepGrid

Usage

```
settings(...)
```

Arguments

`...` Use parameter value pairs (`par1=val1, par2=val2`) to change a parameter. Use parameter names to request parameter's value (`"par1", "par2"`).

Note

Currently the following parameters can be changed, ordered by topic. The default value is shown in the brackets at the end of a line.

Printing grid to the console

- `show.scale` Show grid scale info? (`TRUE`)
- `show.meta` Show grid meta data? (`TRUE`)
- `show.trim` Number of chars to trim strings to (`30`)
- `show.cut` Maximum number of characters printed on the sides of a grid (`20`)
- `c.no` Print construct ID number? (`TRUE`)
- `e.no` Print element ID number? (`TRUE`)

Examples

```
## Not run:
# get current settings
settings()

# get some parameters
settings("show.scale", "show.meta")

# change parameters
bell2010

settings(show.meta=F)
bell2010

settings(show.scale=F, show.cut=30)
bell2010

## End(Not run)
```

`settingsLoad` *Load OpenRepGrid settings*

Description

OpenRepGrid settings saved in an a settings file with the extension `.orgset` can be loaded to restore the settings.

Usage

```
settingsLoad(file)
```

Arguments

`file`	Path of the file to be loaded. If a path is not supplied an interactive file chooser dialog is opened.

`settingsSave` *Save OpenRepGrid settings*

Description

The current settings of OpenRepGrid can be saved into a file with the extension `.orgset`.

Usage

```
settingsSave(file)
```

Arguments

`file`	Path of the file to be saved to. If a path is not supplied an interactive file saver dialog is opened.

`shift` *Shift construct or element to first position.*

Description

Shifts the whole grid vertically or horizontally so that the order remains the same but the prompted element or construct appears in first position.

Usage

```
shift(x, c = 1, e = 1)
```

Arguments

`x`	`repgrid` object.
`c`	Index of construct to be shifted to first position.
`e`	Index of element to be shifted to first position.

Value

`repgrid` object.

Author(s)

Mark Heckmann

Examples

```
## Not run:

   # shift element 13: 'Ideal self' to first position
   shift(feixas2004, 13)

   x <- randomGrid(5,10)
   shift(x, 3, 5)

## End(Not run)
```

show,repgrid-method *Show method for repgrid*

Description

Show method for repgrid

Usage

```
## S4 method for signature 'repgrid'
show(object)
```

Arguments

object	A repgrid object.

statsElements *Descriptive statistics for constructs and elements of a grid.*

Description

Descriptive statistics for constructs and elements of a grid.

Descriptive statistics for constructs and elements of a grid.

Usage

```
statsElements(x, index = TRUE, trim = 20)

statsConstructs(x, index = T, trim = 20)
```

Arguments

x	repgrid object.
index	Whether to print the number of the element.
trim	The number of characters an element or a construct is trimmed to (default is 20). If NA no trimming occurs. Trimming simply saves space when displaying correlation of constructs or elements with long names.

Value

A dataframe containing the following measures is returned invisibly (see describe):
item name
item number
number of valid cases
mean standard deviation
trimmed mean (with trim defaulting to .1)
median (standard or interpolated)
mad: median absolute deviation (from the median)
minimum
maximum
skew
kurtosis
standard error

Note

Note that standard deviation and variance are estimations, i.e. including Bessel's correction. For more info type ?describe.

Note that standard deviation and variance are estimated ones, i.e. including Bessel's correction. For more info type ?describe.

## Not run:

   statsConstructs(fbb2003)
   statsConstructs(fbb2003, trim=10)
   statsConstructs(fbb2003, trim=10, index=F)

   statsElements(fbb2003)
   statsElements(fbb2003, trim=10)
   statsElements(fbb2003, trim=10, index=F)

   # save the access the results
   d <- statsElements(fbb2003)
   d
   d["mean"]
   d[2, "mean"]  # mean rating of 2nd element

   d <- statsConstructs(fbb2003)
   d
   d["sd"]
   d[1, "sd"]   # sd of ratings on first construct
```

```
## End(Not run)
```

`swapConstructs` *Swap the position of two constructs in a grid.*

Description

Swap the position of two constructs in a grid.

Usage

```
swapConstructs(x, pos1 = 1, pos2 = 1)
```

Arguments

`x`	`repgrid` object.
`pos1`	Row number of first construct to be swapped (default=1).
`pos2`	Row number of second construct to be swapped (default=1).

Value

`repgrid` object

Author(s)

Mark Heckmann

Examples

```
## Not run:

   x <- randomGrid()
   swapConstructs(x, 1, 3)       # swap constructs 1 and 3
   swapConstructs(x, 1:2, 3:4)   # swap construct 1 with 3 and 2 with 4

## End(Not run)
```

swapElements — *Swap the position of two elements in a grid.*

Description

Swap the position of two elements in a grid.

Usage

```
swapElements(x, pos1 = 1, pos2 = 1)
```

Arguments

x	repgrid object.
pos1	Column number of first element to be swapped (default=1).
pos2	Column number of second element to be swapped (default=1).

Value

repgrid object.

Author(s)

Mark Heckmann

Examples

```
## Not run:
   x <- randomGrid()
   swapElements(x, 1, 3)       # swap elements 1 and 3
   swapElements(x, 1:2, 3:4)   # swap element 1 with 3 and 2 with 4

## End(Not run)
```

swapPoles — *Swaps the construct poles.*

Description

Swaps the constructs poles and re-adjusts ratings accordingly.

Usage

```
swapPoles(x, pos)
```

Arguments

x	repgrid object.
pos	Row number of construct whose poles are swapped

Value

repgrid object.

Note

Please note that the scale of the rating grid has to be set in order to swap poles. If the scale is unknown no swapping occurs and a warning is issued on the console.

Author(s)

Mark Heckmann

Examples

```
## Not run:

   x <- randomGrid()
   swapPoles(x, 1)     # swap construct poles of construct
   swapPoles(x, 1:2)   # swap construct poles of construct 1 and 2
   swapPoles(x)        # swap all construct poles

## End(Not run)
```

[,repgrid-method *Extract parts of the repgrid object.*

Description

Methods for "[", i.e., subsetting of repgrid objects.

Usage

```
## S4 method for signature 'repgrid'
x[i, j, ..., drop = TRUE]
```

Arguments

x	A repgrid object.
i,j	Row and column indices.
...	Not evaluated.
drop	Not used.

Author(s)

Mark heckmann

Examples

```
x <- randomGrid()
   x[1:4, ]
   x[ , 1:3]
   x[1:4,1:3]
   x[1,1]
```

[<-,repgrid-method   *Method for "<-" assignment of the repgrid ratings.*

Description

It should be possible to use it for ratings on all layers.

Usage

```
## S4 replacement method for signature 'repgrid'
x[i, j, ...] <- value
```

Arguments

x	A repgrid object.
i,j	Row and column indices.
...	Not evaluated.
value	Numeric replacement value(s).

Author(s)

Mark Heckmann

Examples

```
## Not run:
   x <- randomGrid()
   x[1,1] <- 2
   x[1, ] <- 4
   x[ ,2] <- 3

## End(Not run)
```
