

# Package ‘lifecontingencies’

July 2, 2014

**Type** Package

**Title** A package to perform actuarial mathematics for life contingencies insurances

**Version** 1.1

**Date** 2014-05-01

**Author** Giorgio Alfredo Spedicato with contributions from Reinhold Kainhofer and Kevin J. Owens

**Maintainer** Giorgio Alfredo Spedicato <spedicato\_giorgio@yahoo.it>

**Description** Financial and actuarial functions to evaluate life contingencies.

**Depends** R ( $\geq 2.14$ ), methods

**Imports** parallel, utils

**Suggests** demography, forecast, markovchain

**License** GPL-2

**LazyLoad** yes

**BugReports** Giorgio A. Spedicato <lifecontingencies@statisticaladvisor.com>

**BuildVignettes** yes

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2014-05-01 14:54:15

**R topics documented:**

lifecontingencies-package

*Package to perform actuarial mathematics on life contingencies and classical financial mathematics calculations.*

**Description**

The lifecontingencies package performs standard financial, demographic and actuarial mathematics calculation. The main purpose of the package is to provide a comprehensive set of tools to perform risk assessment of life contingent insurances.

**Details**

Package:	lifecontingencies
Type:	Package
Version:	1.1
Date:	2014-05-01
License:	GPL-2.0
LazyLoad:	yes

**Warning**

This package and functions herein are provided as is, without any guarantee regarding the accuracy of calculations. The author disclaims any liability arising by any losses due to direct or indirect use of this package.

**Note**

Work in progress.

**Author(s)**

Giorgio Alfredo Spedicato with contributions from Reinhold Kainhofer and Kevin J. Owens Maintainer: <spedicato\_giorgio@yahoo.it>

**References**

```
##financial mathematics example

#calculates monthly installment of a loan of 100,000,
#interest rate 0.05

i=0.05
monthlyInt=(1+i)^(1/12)-1
Capital=100000
#Montly installment

R=1/12*Capital/annuity(i=i, n=10,k=12, type = "immediate")
R
balance=numeric(10*12+1)
capitals=numeric(10*12+1)
interests=numeric(10*12+1)
balance[1]=Capital
interests[1]=0
capitals[1]=0

for(i in (2:121)) {
balance[i]=balance[i-1]*(1+monthlyInt)-R
interests[i]=balance[i-1]*monthlyInt
capitals[i]=R-interests[i]
}
loanSummary=data.frame(rate=c(0, rep(R,10*12)),
balance, interests, capitals)

head(loanSummary)

tail(loanSummary)

##actuarial mathematics example

#APV of an annuity
```

```

data(sofar)
sofarAct=with(sofar, new("actuarialtable",interest=0.06,
x=x,lx=Ix,name="SOA2008"))
#evaluate and life-long annuity for an aged 65
axn(sofarAct, x=65)

```

---

accumulatedValue      *Function to evaluate the accumulated value.*

---

### Description

This functions returns the value at time n of a series of equally spaced payments of 1.

### Usage

```
accumulatedValue(i, n,m=0, k,type = "immediate")
```

### Arguments

i	Effective interest rate expressed in decimal form. E.g. 0.03 means 3%.
n	Number of terms of payment.
m	Deferring period, whose default value is zero.
k	Frequency of payment.
type	A string, either "immediate" or "due".

### Details

The accumulated value is the future value of the terms of an annuity. Its mathematical expression is  $s_{\overline{n}|} = (1 + i)^n a_{\overline{n}|}$

### Value

A numeric value representing the calculated accumulated value.

### Warning

The function is provided as is, without any guarantee regarding the accuracy of calculation. We disclaim any liability for eventual losses arising from direct or indirect use of this software.

### Note

Accumulated value are derived from annuities by the following basic equation  $s_{\overline{n}|} = (1 + i)^n a_{\overline{n}|}$ .

### Author(s)

Giorgio A. Spedicato

**References**

Broverman, S.A., Mathematics of Investment and Credit (Fourth Edition), 2008, ACTEX Publications.

**See Also**

[annuity](#)

**Examples**

```
#A man wants to save 100,000 to pay for his sons
#education in 10 years time. An education fund requires the investors to
#deposit equal installments annually at the end of each year. If interest of
#0.075 is paid, how much does the man need to save each year in order to
#meet his target?
R=100000/accumulatedValue(i=0.075,n=10)
```

---

actuarialtable-class    *Class "actuarialtable"*

---

**Description**

Objects of class "actuarialtable" inherit the structure of class "lifetable" adding just the slot for interest rate, interest.

**Objects from the Class**

Objects can be created by calls of the form `new("actuarialtable", ...)`. Creation is the same as lifetable objects creation, the slot for interest must be added too.

**Slots**

**interest:** Object of class "numeric" slot for interest rate, e.g. 0.03

**x:** Object of class "numeric" age slot

**lx:** Object of class "numeric" subjects at risk at age x

**name:** Object of class "character" name of the actuarial table

**Extends**

Class "[lifetable](#)", directly.

**Methods**

**coerce** signature(from = "actuarialtable", to = "data.frame"): it converts to a data.frame object

**show** signature(object = "actuarialtable"): it shows classical commutation functions

**print** signature(x = "actuarialtable"): as show

**summary** signature(object = "actuarialtable"): it returns summary information about the object

**Warning**

The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Note**

The interest slot will handle time-varying interest rates in the future.

**Author(s)**

Giorgio A. Spedicato

**References**

```

---

AExn

*Function to evaluate the n-year endowment insurance*

---

**Description**

This function evaluates the n-year endowment insurance.

**Usage**

```
AExn(actuarialtable, x, n, i=actuarialtable@interest, k = 1, type = "EV", power=1)
```

**Arguments**

actuarialtable	An actuarial table object.
x	Insured age.
n	Length of the insurance.
i	Rate of interest. When missing the one included in the actuarialtable object is used.
k	Frequency of benefit payment.
type	Character value, either "EV" or "ST". EV is the default value.
power	The power of the APV. Default is 1 (mean)

**Details**

The n-year endowment insurance provides a payment either in the year of death or at the end of the insured period.

**Value**

A numeric value.

**Note**

When type="EV" the function calls both Axn and Exn.

**Author(s)**

Giorgio A. Spedicato

**References**

Actuarial Mathematics (Second Edition), 1997, by Bowers, N.L., Gerber, H.U., Hickman, J.C., Jones, D.A. and Nesbitt, C.J.

**See Also**

[Axn,Exn](#)

**Examples**

```
#Actuarial Mathematics book example
#check the actuarial equality on the expected values Exn+Axn=AExn
data(soa08Act)
AExn(soa08Act, x=35,n=30,i=0.06)
Exn(soa08Act, x=35,n=30,i=0.06)+Axn(soa08Act, x=35,n=30,i=0.06)
```

---

annuity

*Annuity function*

---

**Description**

Function to calculate present value of annuities-certain.

**Usage**

```
annuity(i, n,m=0, k=1,type = "immediate")
```

**Arguments**

i	Effective interest rate expressed in decimal form. E.g. 0.03 means 3%. It can be a vector of interest rates of the same length of periods.
n	Periods for payments. If $n = \text{infinity}$ then annuity returns the value of a perpetuity (either immediate or due).
m	Deferring period, whose default value is zero.
k	Yearly payments frequency. A payment of $k^{-1}$ is supposed to be performed at the end of each year.
type	A string, either "immediate" or "due".

**Details**

This function calculates the present value of a stream of fixed payments separated by equal interval of time. Annuity immediate has the first payment at time  $t=0$ , while an annuity due has the first payment at time  $t=1$ .

**Value**

A string, either "immediate" or "due".

**Note**

The value returned by annuity function derives from direct calculation of the discounted cash flow and not from formulas, like  $a^{(m)}_{\overline{n}|} = \frac{1-v^n}{i^{(m)}}$ . When  $m$  is greater than 1, the payment per period is assumed to be  $\frac{1}{m}$ .

**Author(s)**

Giorgio A. Spedicato

**References**

Broverman, S.A., Mathematics of Investment and Credit (Fourth Edition), 2008, ACTEX Publications.

**See Also**

[accumulatedValue](#)

**Examples**

```
# The present value of 5 payments of 1000 at one year interval that begins
# now when the interest rate is 2.5% is
1000*annuity(i=0.05, n=5, type = "due")
#A man borrows a loan of 20,000 to purchase a car at
# a nominal annual rate of interest of 0.06. He will pay back the loan through monthly
#installments over 5 years, with the first installment to be made one month
#after the release of the loan. What is the monthly installment he needs to pay?
R=20000/annuity(i=0.06/12, n=5*12)
```

---

Axn

*Function to evaluate life insurance.*

---

**Description**

This function evaluates n - years term and whole life insurance.

**Usage**

```
Axn(actuarialtable, x, n, i=actuarialtable@interest,m, k=1, type = "EV",power=1)
```

**Arguments**

actuarialtable	An actuarial table object.
x	Age of the insured.
n	Coverage period, if missing the insurance is considered whole life $n = \omega - x - m$
i	Interest rate (overrides the interest rate slot in actuarialtable).
m	Deferring period, even fractional, if missing assumed to be 0.
k	Number of periods per year at the end of which the capital is payable in case of insured event, default=1 (capital payable at the end of death year).
type	A character value, either "EV" (default value) or "ST".
power	The power of the APV. Default is 1 (mean)

**Details**

The variance calculation has not been implemented yet.

**Value**

A numeric value representing either the actuarial value of the coverage (when type="EV") or a number drawn from the underlying distribution of Axn.

**Warning**

The function is provided as is, without any guarantee regarding the accuracy of calculation. We disclaim any liability for eventual losses arising from direct or indirect use of this software.

**Note**

It is possible that value returned by stochastic simulation are biased. Successive releases of this software will analyze the issue with detail.

**Author(s)**

Giorgio A. Spedicato

**References**

Actuarial Mathematics (Second Edition), 1997, by Bowers, N.L., Gerber, H.U., Hickman, J.C., Jones, D.A. and Nesbitt, C.J.

**See Also**

[axn](#), [Exn](#)

**Examples**

```
#assume SOA example life table to be load
data(sofar)
sofarAct=with(sofar, new("actuarialtable",interest=0.06,
x=x,lx=lx,name="SOA2008"))
#evaluate the value of a 40 years term life insurance for an aged 25
Axn(actuarialtable=sofarAct, x=25, n=40)
#check an relevant life contingencies relationship
k=12
i=0.06
j=real2Nominal(i,k)
Axn(sofarAct, 30,k=12)
i/j*Axn(sofarAct, 30,k=1)
```

---

axn

*Annuity immediate and due function.*

---

**Description**

This function calculates actuarial value of annuities, given an actuarial table. Fractional and deferred annuities can be evaluated. Moreover it can be used to simulate the stochastic distribution of the annuity value.

**Usage**

```
axn(actuarialtable, x, n, i = actuarialtable@interest, m, k = 1, type = "EV",
    power=1, payment = "advance")
```

**Arguments**

actuarialtable	An actuarial table object.
x	Age of the annuitant.
n	Number of terms of the annuity, if missing annuity is intended to be paid until death.
i	Interest rate (default value the interest of the life table).
m	Deferring period. Assumed to be 1 whether missing.
k	Number of fractional payments per period. Assumed to be 1 whether missing.
type	A string, either "EV" (default value) or "ST" (stochastic realization).
power	The power of the APV. Default is 1 (mean)
payment	Payment type: "advance" default is the annuity due, otherwise annuity immediate.

**Details**

When "ST" has been selected a stochastic value representing a number drawn from the domain of

$$a_x^n$$

is drawn. "EV" calculates the classical APV.

**Value**

A numeric value.

**Warning**

The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Note**

When either  $x = \omega$  or  $n = 0$  zero is returned.

**Author(s)**

Giorgio A. Spedicato

**References**

Actuarial Mathematics (Second Edition), 1997, by Bowers, N.L., Gerber, H.U., Hickman, J.C., Jones, D.A. and Nesbitt, C.J.

**See Also**[annuity](#), [Exn](#)**Examples**

```
#assume SOA example life table to be load
data(sofar)
sofarAct=with(sofar, new("actuarialtable",interest=0.06,
x=x,lx=lx,name="SOA2008"))
#evaluate and life-long annuity for an aged 65
axn(sofarAct, x=65)
```

axyn

*Functions to evaluate life insurance and annuities on two heads.***Description**

These functions evaluates life insurances and annuities on two heads.

**Usage**

```
axyn(tablex, tabley, x, y, n, i, m, k = 1, status = "joint", type = "EV",
payment="advance")
Axyn(tablex, x, tabley, y, n, i, m, k = 1, status = "joint", type = "EV")
```

**Arguments**

tablex	Life X lifetable object.
tabley	Life Y lifetable object.
x	Age of life X.
y	Age of life Y.
n	Insured duration. Infinity if missing.
i	Interest rate. Default value is those implied in actuarialtable.
m	Deferring period. Default value is zero.
k	Fractional payments or periods where insurance is payable.
status	Either "joint" or "last" survival status.
type	"EV" (expected value) or "ST" (stochastic)
payment	Payment type: "advance" default is the annuity due, otherwise annuity immediate.

**Details**

Actuarial mathematics book formulas has been implemented.

**Value**

A numeric value returning APV of chosen insurance form.

**Warning**

The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Note**

These functions have not been tested carefully.

**Author(s)**

Giorgio A. Spedicato

**References**

Actuarial Mathematics (Second Edition), 1997, by Bowers, N.L., Gerber, H.U., Hickman, J.C., Jones, D.A. and Nesbitt, C.J.

**See Also**

[pxyt](#)

**Examples**

```
data(soa08Act)
#last survival status annuity
axyz(tablex=soa08Act, tabley=soa08Act, x=65, y=70,
n=5, status = "last",type = "EV")
#first survival status annuity
Axyz(tablex=soa08Act, tabley=soa08Act, x=65, y=70,
status = "last",type = "EV")
```

---

Axyzn

*Multiple lives insurances and annuities*

---

**Description**

Function to evaluate the multiple lives insurances and annuities

**Usage**

```
Axyzn(tablesList, x, n, i, m, k = 1, status = "joint", type = "EV",
power=1)
axyzn(tablesList, x, n, i, m, k = 1, status = "joint", type = "EV",
power=1, payment="advance")
```

**Arguments**

tablesList	A list whose elements are either lifetable or actuarialtable class objects.
x	A vector of the same size of tableList that contains the initial ages.
n	Length of the insurance.
i	Interest rate
m	Deferring period.
k	Fractional payment frequency.
status	Either "joint" (for the joint-life status model) or "last".
type	"EV", for expected value. "ST" for stochastic value.
power	The power of the APV. Default is 1 (mean).
payment	Payment type: "advance" default is the annuity due, otherwise annuity due.

**Details**

In theory, these functions apply the same concept of life insurances on one head on multiple heads.

**Value**

The insurance value is returned.

**Note**

These functions are the more general version of [axyn](#) and [Axyn](#).

**Author(s)**

Giorgio Alfredo Spedicato, Kevin J. Owens.

**References**

Broverman, S.A., Mathematics of Investment and Credit (Fourth Edition), 2008, ACTEX Publications.

sofarAct=with(sofar, new("actuarialtable", interest=0.06,
x=x, lx=lx, name="SOA2008"))
#evaluate and life-long annuity for an aged 65
listOfTables=list(sofarAct, sofarAct)
#Check actuarial equality
axyzn(listOfTables, x=c(60,70), status="last")
axn(listOfTables[[1]], 60)+axn(listOfTables[[2]], 70)-
axyzn(listOfTables, x=c(60,70), status="joint")
```

---

coerce-methods                      *Methods for Function coerce*

---

### Description

Function `coerce` transforms `lifetable` or `actuarialtable` objects in `data.frame` objects.

### Methods

`signature(from = "actuarialtable", to = "data.frame")` `coerce` method applied to an `actuarialtable` object to obtain a `data.frame` object.

`signature(from = "lifetable", to = "data.frame")` `coerce` method applied to an `actuarialtable` object to obtain a `data.frame` object.

`signature(from = "data.frame", to = "lifetable")` `coerce` method applied to a `data.frame` object to obtain a `lifetable` object. Requires columns "lx" and "x" present.

`signature(from = "actuarialtable", to = "numeric")` It returns the underlying whole life insurance APV.

`signature(from = "lifetable", to = "numeric")` It returns the underlying yearly mortality rate.

---

DAXn                                      *Decreasing life insurance*

---

### Description

This function evaluates the n-year term decreasing life insurance. Both actuarial value and stochastic random sample can be returned.

### Usage

```
DAXn(actuarialtable, x, n,
      i=actuarialtable@interest,m = 0,k=1,
      type = "EV", power=1)
```

### Arguments

`actuarialtable` An actuarial table object.

`x` Age of the insured.

`n` Length of the insurance period.

`i` Interest rate, when present it overrides the interest rate of the actuarial table object.

`m` Deferring period, even fractional, assumed 1 whether missing.

`k` Number of fractional payments per period. Assumed to be 1 whether missing.

type	Default value is "EV", where APV is returned. "ST" returns a sample from the underlying present value of benefits distribution.
power	The power of the APV. Default is 1 (mean)

### Details

Formulas of Bowes book have been implemented.

### Value

A numeric value representing the expected value or the simulated value.

### Warning

The function is provided as is, without any guarantee regarding the accuracy of calculation. We disclaim any liability for eventual losses arising from direct or indirect use of this software.

### Note

Neither fractional payments nor stochastic calculations have been implemented yet.

### Author(s)

Giorgio A. Spedicato

### References

Actuarial Mathematics (Second Edition), 1997, by Bowers, N.L., Gerber, H.U., Hickman, J.C., Jones, D.A. and Nesbitt, C.J.

### See Also

[Axn, IAxn](#)

### Examples

```
#using SOA illustrative life tables
data(sofar)
sofarAct=with(sofar, new("actuarialtable", interest=0.06,
x=x, lx=lx, name="SOA2008"))
#evaluate the value of a 10 years decreasing term life insurance for an aged 25
DAxn(actuarialtable=sofarAct, x=25, n=10)
```

---

decreasingAnnuity      *Function to evaluate decreasing annuities.*

---

**Description**

This function return present values for decreasing annuities - certain.

**Usage**

```
decreasingAnnuity(i, n, type="immediate")
```

**Arguments**

i	A numeric value representing the interest rate.
n	The number of periods.
type	A character value, specifying the annuity type. Either "immediate" or "due". Default value is "immediate".

**Details**

A decreasing annuity has the following flows of payments:  $n, n-1, n-2, \dots, 1, 0$ .

**Value**

A numeric value reporting the present value of the decreasing cash flows.

**Warning**

The function is provided as is, without any guarantee regarding the accuracy of calculation. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Note**

This function calls presentValue function internally.

**Author(s)**

Giorgio A. Spedicato

demoIta

*Italian population life tables for males and females***Description**

This dataset reports five pairs of Italian population life tables. These table can be used to create life table objects and actuarial tables object.

**Usage**

```
data(demoIta)
```

**Format**

A data frame with 121 observations on the following 9 variables.

*X* a numeric vector, representing ages from 0 to  $\omega$ .

*SIM92* a numeric vector, 1992 cross section general population males life table

*SIF92* a numeric vector, 1992 cross section general population females life table

*SIM00* a numeric vector, 2000 cross section general population males life table

*SIF00* a numeric vector, 2000 cross section general population males life table

*SIM02* a numeric vector, 2002 cross section general population females life table

*SIF02* a numeric vector, 2002 cross section general population males life table

*RG48M* a numeric vector, RG48 projected males life table

*RG48F* a numeric vector, RG48 projected females life table

*IPS55M* a numeric vector, IPS55 projected males life table

*IPS55F* a numeric vector, IPS55 projected females life table

*SIM31* a numeric vector, 1931 criss sectional general population males life table

*SIM51* a numeric vector, 1951 criss sectional general population males life table

*SIM61* a numeric vector, 1961 criss sectional general population males life table

*SIF61* a numeric vector, 1931 criss sectional general population females life table

*SIM71* a numeric vector, 1971 criss sectional general population males life table

*SIM81* a numeric vector, 1981 criss sectional general population males life table

*SIF81* a numeric vector, 1981 criss sectional general population females life table

**Details**

These table contains the vectors of survival at the beginning of life years and are the building block of both [lifetable](#) and [actuarialtable](#) classes.

**Source**

These tables comes from Italian national statistical bureau (ISTAT) for SI series, government Ministry of Economics (Ragioneria Generale dello Stato) for RG48 or from Insurers' industrial association IPS55. RG48 represents the projected survival table for the 1948 born cohort, while IPS55 represents the projected survival table for the 1955 born cohort.

demoUk

*UK life tables*

---

**Description**

AM and AF one year mortality rate. Series of 1992

**Usage**

```
data(demoUk)
```

**Format**

A data frame with 74 observations on the following 3 variables.

Age age

AM92 one year mortality rate for males

AF92 one year mortality rate for females

**Details**

This data set shows the one year survival rates for males and females of the 1992 series. It has been taken from the Institute of Actuaries. The series cannot be directly used to create a life table since neither rates are not provided for ages below 16 nor for ages over 90. Various approach can be used to complete the series.

demoUsa

*United States Social Security life tables*

---

## Description

This data set contains period life tables for years 1990, 2000 and 2007. Both males and females life tables are reported.

## Usage

```
data(demoUsa)
```

**Format**

A data frame with 114 observations on the following 7 variables.

age age vector

USSS2007M 2007 male life table

USSS2007F 2007 female life table

USSS2000M 2000 male life table

USSS2000F 2000 female life table

USSS1990M 1990 male life table

USSS1990F 1990 female life table

**Details**

Reported age is truncated at the last age with  $lx > 0$ .

duration

*Functions to evaluate duration and convexity*

---

**Description**

These functions evaluate the duration or the convexity of a series of cash flows

**Usage**

```
duration(cashFlows, timeIds, i, k = 1, macaulay = TRUE)
```

```
convexity(cashFlows, timeIds, i, k = 1)
```

**Arguments**

cashFlows	A vector representing the cash flows amounts.
timeIds	Cash flows times
i	APR interest, i.e. nominal interest rate compounded m-thly.
k	Compounding frequency for the nominal interest rate $i$ .
macaulay	Is the macaulay duration (default value) or the effective duration to be evaluated?

**Details**

The Macaulay duration is defined as  $\sum_t \frac{t * CF_t (1 + \frac{i}{k})^{-t * k}}{P}$ , while  $\sum_t t * (t + \frac{1}{k}) * CF_t (1 + \frac{y}{k})^{-k * t - 2}$

**Value**

A numeric value representing either the duration or the convexity of the cash flow series

**Note**

Vectorial interest rate are not handled yet.

**Author(s)**

Giorgio A. Spedicato

**References**

#evaluate the duration of a coupon payment
cf=c(10,10,10,10,10,110)
t=c(1,2,3,4,5,6)
duration(cf, t, i=0.03)
#and the convexity

convexity(cf, t, i=0.03)
```

---

effective2Convertible *Function to switch from nominal / effective / convertible rates*

---

**Description**

This function provides convenience functions to switch from effective to convertible rate.

**Usage**

```
effective2Convertible(i, k = 1, type = "interest")
```

```
convertible2Effective(i, k = 1, type = "interest")
```

```
nominal2Real(i, k = 1, type = "interest")
```

```
real2Nominal(i, k = 1, type = "interest")
```

**Arguments**

i	The rate to be converted.
k	The original / target compounding frequency.
type	Either "interest" (default) or "nominal".

**Details**

effective2Convertible and convertible2Effective wrap the other two functions.

**Value**

A numeric value.

**Warning**

The function is provided as is without any guarantee of results.

**Note**

Convertible rates are synonyms of nominal rates

**Author(s)**

Giorgio A. Spedicato

**References**

Broverman, S.A., *Mathematics of Investment and Credit (Fourth Edition)*, 2008, ACTEX Publications.

---

Exn	<i>Function to evaluate the pure endowment.</i>
-----	---

---

**Description**

Given an actuarial table, this function evaluate the pure endowment.

**Usage**

```
Exn(actuarialtable, x, n, i=actuarialtable@interest, type = "EV", power=1)
```

**Arguments**

actuarialtable	An actuarial table object.
x	Age of the insured.
n	Length of the pure endowment.
i	Interest rate (overrides the interest rate of the actuarial table object)
type	A string, either "EV" (default value), "ST" (stochastic realization) or "VR" if the value of the variance is needed.
power	The power of the APV. Default is 1 (mean)

**Details**

As done in all package, interest rate is assumed fixed.

**Value**

The value of the pure endowment.

**Warning**

The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

Exn(sofarAct, x=30, n=35)
```

---

exn

*Function/method to calculate the expected life.*

---

**Description**

This method calculates the expected life span between ages  $x$  and  $x+n$ .

**Usage**

```
exn(object, x, n, type="curtate")
```

**Arguments**

object	A lifetable object.
x	Age from which the life span should be calculated.
n	Time until which the expected life should be calculated. Assumed omega - x whether missing.
type	Either complete or curtate

**Value**

A numeric value representing the expected life span.

**Warning**

getDecrements(newMdt)
```

---

getLifecontingencyPv *Functions to obtain the present value of a life contingency given the time to death*

---

**Description**

It returns the present value of a life contingency, specified by its APV symbol, known the time to death of the subjects

**Usage**

```
getLifecontingencyPv(deathsTimeX, lifecontingency, object, x, t, i = object@interest,
m = 0, k = 1, payment = "advance")
getLifecontingencyPvXyz(deathsTimeXyz, lifecontingency, tablesList, x, t, i, m = 0,
k = 1, status = "joint", payment = "advance")
```

**Arguments**

deathsTimeX	Time to death
lifecontingency	lifecontingency symbol
object	life table(s)
x	age(s) of the policyholder(s)
t	term of the contract
i	interest rate
m	deferment
k	fractional payments

payment	either "advance" or "deferred"
deathsTimeXyz	matrix of death times from birth
tablesList	list of table of the same size of num column of deathTimeXyz.
status	"joint" or "last" survivor.

**Details**

This function is a wrapper to the many internal functions that give the PV known the age of death.

**Value**

A vector or matrix of size number of rows of deathTimeXyz / deathTimeXy

**Warning**

The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Note**

Multiple life function needs to be tested

ncol=2),
lifecontingency = "Axyz", tablesList = list(soa08Act, soa08Act), i = 0.03, t=30, x=c(40,50),
m=0, k=1, status="last")
testgetLifecontingencyPvAxn<-getLifecontingencyPv(deathsTimeX = seq(0, 110, by=1),
lifecontingency = "Axn", object=soa08Act,
x=40, t=20, m=0, k=1)
```

---

`getOmega`*Function to return the terminal age of a life table.*

---

**Description**

This function returns the  $\omega$  value of a life table object, that is, the last attainable age within a life table.

**Usage**

```
getOmega(object)
```

**Arguments**

`object`            A life table object.

**Value**

A numeric value representing the  $\omega$  value of a life table object

**Warning**

The function is provided as is, without any guarantee regarding the accuracy of calculation. We disclaim any liability for eventual losses arising from direct or indirect use of this software.

**Author(s)**

Giorgio A. Spedicato

signature(x = "lifetable") A lifetable object.

---

IAXn	<i>Increasing life insurance</i>
------	----------------------------------

---

**Description**

This function evaluates the APV of an increasing life insurance. The amount payable at the end of year of death are:  $1, 2, \dots, n - 1, n$ . N can be set as  $\omega - x - 1$ .

**Usage**

IAXn(actuarialtable, x, n,i=actuarialtable@interest, m = 0, k=1, type = "EV", power=1)

**Arguments**

actuarialtable	The actuarial table used to perform life - contingencies calculations.
x	The age of the insured.
n	The term of life insurance. If missing n is set as $n = \omega - x - m - 1$ .
i	Interest rate (overrides the interest rate of the actuarialtable object).
m	The deferring period. If missing, m is set as 0.
k	Number of fractional payments per period. Assumed to be 1 whether missing.
type	Default value is "EV", where APV is returned. "ST" returns a sample from the underlying present value of benefits distribution.
power	The power of the APV. Default is 1 (mean).

**Details**

The stochastic value feature has not been implemented yet.

**Value**

A numeric value.

**Warning**

The function is provided as is, without any guarantee regarding the accuracy of calculation. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Author(s)**

Giorgio A. Spedicato

Iaxn(actuarialtable=sofarAct, x=80, n=10)
```

---

increasingAnnuity	<i>Increasing annuity.</i>
-------------------	----------------------------

---

**Description**

This function evaluates non - stochastic increasing annuities.

**Usage**

```
increasingAnnuity(i, n, type = "immediate")
```

**Arguments**

i	A numeric value representing the interest rate.
n	The number of periods.
type	Type of annuity. Either "immediate" or "due".

**Details**

An increasing annuity shows the following flow of payments:  $1, 2, \dots, n - 1, n$

**Value**

The value of the annuity.

**Warning**

The function is provided as is, without any guarantee regarding the accuracy of calculation. We disclaim any liability for eventual losses arising from direct or indirect use of this software.

**Note**

This function calls internally presentValue function.

lifetable-class	<i>Class "lifetable"</i>
-----------------	--------------------------

---

**Description**

`lifetable` objects allow to define and use life tables with the aim to evaluate survival probabilities and mortality rates easily. Such values represent the building blocks used to estimate life insurances actuarial mathematics.

**Objects from the Class**

Objects can be created by calls of the form `new("lifetable", ...)`. Two vectors are needed. The age vector and the population at risk vector.

**Slots**

**x:** Object of class "numeric", representing the sequence  $0, 1, \dots, \omega$

**lx:** Object of class "numeric", representing the number of lives at the beginning of age  $x$ . It is a non increasing sequence. The last element of vector `x` is supposed to be  $> 0$ .

**name:** Object of class "character", reporting the name of the table

**Methods**

**coerce** signature(from = "lifetable", to = "data.frame"): method to create a data - frame from a lifetable object

**plot** signature(x = "lifetable"): method to plot the survival probability implied in the table

**show** signature(object = "lifetable"): identical to plot method

**coerce** signature(from = "lifetable", to = "markovchainList"): coerce method from lifetable to markovchainList

**summary** signature(object = "lifetable"): it returns summary information about the object

**Warning**

The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Note**

t may be missing in pxt, qxt, ext. It assumes value equal to 1 in such case.

**Author(s)**

Giorgio A. Spedicato

**References**

Actuarial Mathematics (Second Edition), 1997, by Bowers, N.L., Gerber, H.U., Hickman, J.C., Jones, D.A. and Nesbitt, C.J.

---

Lxt

*Number of person - years lived.*

---

**Description**

This function calculates the Lxt demographic function.

**Usage**

```
Lxt(object, x, t = 1, fxt = 0.5)
```

**Arguments**

object	A lifetable object.
x	Age.
t	Length of the period.
fxt	separation factor, default value is 0.5 (half year).

**Details**

The separation factor is the average number of years not lived between exact ages  $x$  and  $x+t$  for those who die between exact ages  $x$  and  $x+t$

**Value**

An integer value

**Warning**

The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Note**

This function is used in life tables analysis

---

`mdt-class`*Class "mdt"*

---

### Description

A class to store multiple decrement tables

### Objects from the Class

Objects can be created by calls of the form `new("mdt", name, table, ...)`. They store absolute decrements

### Slots

**name:** The name of the table

**table:** A data frame containing at least the number of decrements

### Methods

**getDecrements** signature(object = "mdt"): return the name of decrements

**getOmega** signature(object = "mdt"): maximum attainable age

**initialize** signature(.Object = "mdt"): method to initialize the class

**print** signature(x = "mdt"): tabulate absolute decrement rates

**show** signature(object = "mdt"): show rates of decrement

**coerce** signature(from = "mdt", to = "markovchainList"): coercing to markovchainList objects

**coerce** signature(from = "mdt", to = "data.frame"): coercing to markovchainList objects

**summary** signature(object = "mdt"): it returns summary information about the object

### Note

Currently only decrements storage of the class is defined.

### Author(s)

Giorgio Spedicato

**Examples**

```
#shows the class definition
showClass("mdt")
#create a new table
tableDecr=data.frame(d1=c(150,160,160),d2=c(50,75,85))
newMdt<-new("mdt",name="testMDT",table=tableDecr)
```

---

multiple life probabilities

*Functions to deals with multiple life models*

---

**Description**

These functions evaluate multiple life survival probabilities, either for joint or last life status. Arbitrary life probabilities can be generated as well as random samples of lifes.

**Usage**

```
exyzt(tablesList, x, t = Inf, status = "joint", type = "Kx", ...)
pxyzt(tablesList, x, t, status = "joint", fractional=rep("linear",
length(tablesList)), ...)
qxyzt(tablesList, x, t, status = "joint",
fractional=rep("linear",length(tablesList)), ...)
rLifexyz(n, tablesList, x, k = 1, type = "Tx")
```

**Arguments**

tablesList	A list whose elements are either lifetable or actuarialtable class objects.
x	A vector of the same size of tableList that contains the initial ages.
t	The duration.
n	The size of sampled life duration matrix.
status	Either "joint" (for the joint-life status model) or "last".
type	"Tx" for continuous, "Kx" for curtate.
fractional	Fractional lives assumption.
...	Options to be passed to pxt.
k	Fractional frequency option.

**Details**

These functions extends [pxyt](#) family to an arbitrary number of life contingencies.

**Value**

An estimate of survival / death probability or expected lifetime, or a matrix of ages.

**Note**

The procedure is experimental.

**Author(s)**

Giorgio Alfredo, Spedicato

**References**

**Examples**

```
#assessment of curtate expectation of future lifetime of the joint-life status
#generate a sample of lifes
data(soaLt)
soa08Act=with(soaLt, new("actuarialtable",interest=0.06,x=x,lx=Ix,name="SOA2008"))
tables=list(males=soa08Act, females=soa08Act)
xVec=c(60,65)
test=rLifexyz(n=50000, tablesList = tables,x=xVec,type="Kx")
#check first survival status
t.test(x=apply(test,1,"min"),mu=exyzt(tablesList=tables, x=xVec,status="joint"))
#check last survival status
t.test(x=apply(test,1,"max"),mu=exyzt(tablesList=tables, x=xVec,status="last"))
```

---

mxt

*Central mortality rate.*

---

**Description**

This function returns the central mortality rate demographic function.

**Usage**

```
mxt(object, x, t)
```

**Arguments**

object	A lifetable object
x	Age when the calculation starts.
t	Age when the calculation ends, default=1.

**Details**

The central mortality rate is defined as  $m_{x,t} = \frac{d_{x,t}}{l_{x,t}}$

**Value**

A numeric value representing the central mortality rate between age  $x$  and  $x+t$ .

**Note**

This function is used in demographic analysis.

**Author(s)**

Giorgio A. Spedicato

**References**

plot-methods

*Methods for Function plot*

---

**Description**

Methods for function plot

**Methods**

signature(x = "ANY") This method shows the survival function implied in actuarialtable and lifetable objects.

signature(x = "lifetable") A lifetable (or actuarialtable) object.

---

presentValue	<i>Present value of a series of cash flows.</i>
--------------	---

---

**Description**

This function evaluates the present values of a series of cash flows, given occurrence time. Probabilities of occurrence can also be taken into account.

**Usage**

```
presentValue(cashFlows, timeIds, interestRates, probabilities, power=1)
```

**Arguments**

cashFlows	Vector of cashFlow, must be coherent with timeIds
timeIds	Vector of points of time where cashFlows are due.
interestRates	A numeric value or a time-size vector of interest rate used to discount cash flow.
probabilities	Optional vector of probabilities.
power	Power to square discount and cash flows. Default is set to 1

**Details**

probabilities is optional, a sequence of 1 length of timeIds is assumed. Interest rate shall be a fixed number or a vector of the same size of timeIds. power parameters is generally useless beside life contingencies insurances evaluations.

**Value**

A numeric value representing the present value of cashFlows vector, or the actuarial present value if probabilities are provided.

**Warning**

The function is provided as is, without any guarantee regarding the accuracy of calculation. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Note**

This simple function is the kernel working core of the package. Actuarial and financial mathematics ground on it.

**Author(s)**

Giorgio A. Spedicato

**References**

#assume 3% of interest rate
presentValue(cashFlows=cf, timeIds=t, interestRates=0.03, probabilities=p)
```

---

print-methods	<i>Print method for lifetable objects</i>
---------------	---

---

**Description**

This functions print a lifetable

**Methods**

signature(x = "ANY") A lifetable object.  
signature(x = "lifetable") A lifetable

---

probs2lifetable	<i>Life table from probabilities</i>
-----------------	--------------------------------------

---

**Description**

This function returns a newly created lifetable object given either survival or death (one year) probabilities)

**Usage**

```
probs2lifetable(probs, radix = 10000, type = "px", name = "ungen")
```

**Arguments**

probs	A real valued vector representing either one year survival or death probabilities. The last value in the vector must be either 1 or 0, depending if it represents death or survival probabilities respectively.
radix	The radix of the life table.
type	Character value either "px" or "qx" indicating how probabilities must be interpreted.
name	The character value to be put in the corresponding slot of returned object.

**Details**

The  $\omega$  value is the length of the probs vector.

**Value**

A [lifetable](#) object.

**Warning**

The function is provided as is, without any guarantee regarding the accuracy of calculation. We disclaim any liability for eventual losses arising from direct or indirect use of this software.

**Note**

This function allows to use mortality projection given by other softwares with the lifecontingencies package.

**Author(s)**

Giorgio A. Spedicato

**References**

```

---

pxt

*Functions to evaluate survival, death probabilities and deaths.*

---

### Description

These functions evaluate raw survival and death probabilities between age  $x$  and  $x+t$

### Usage

```
dxt(object, x, t, decrement)
pxt(object, x, t, fractional = "linear", decrement)
qxt(object, x, t, fractional = "linear", decrement)
```

### Arguments

object	A lifetable object.
x	Age of life $x$ .
t	Period until which the age shall be evaluated. Default value is 1.
fractional	Assumptions for fractional age. One of "linear", "hyperbolic", "constant force".
decrement	The reason of decrement (only for mdt class objects). Can be either an ordinal number or the name of decrement

### Details

Fractional assumptions are: -linear: linear interpolation between consecutive ages. -constant force of mortality: constant force of mortality. -hyperbolic: Balducci assumptions. See references for details.

### Value

A numeric value representing requested probability.

### Warning

The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

### Note

Function `dxt` accepts also fractional value of  $t$ . Linear interpolation is used in such case. These functions are called by many other functions.

### Author(s)

Giorgio A. Spedicato

qxt(object=soa08Act, x=90, t=2)
#pxt example
pxt(object=soa08Act, x=90, t=2, "constant force" )
#add another example for MDT
```

---

pxyt

---

*Functions to evaluate joint survival probabilities.*

---

**Description**

These functions evaluate survival and death probabilities for two heads.

**Usage**

```
exyt(objectx, objecty, x, y, t, status = "joint")
pxyt(objectx, objecty, x, y, t, status = "joint")
qxyt(objectx, objecty, x, y, t, status = "joint")
```

**Arguments**

objectx	lifetable for life X.
objecty	lifetable for life Y.
x	Age of life X.
y	Age of life Y.
t	Time until survival has to be evaluated.
status	Either "joint" or "last".

**Value**

A numeric value representing joint survival probability.

**Warning**

The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Note**

These functions are used to evaluate two or more life contingencies.

**Author(s)**

Giorgio A. Spedicato, Kevin J. Owens.

```

---

rLife

*Function to generate random future lifetimes*

---

**Description**

This function returns random samples from the time until death (future lifetime) of a subject aged  $x$ . Either the continuous or the curtate time until death can be returned.

**Usage**

```
rLife(n, object, x = 0, k=1, type = "Tx")
```

**Arguments**

n	Number of variates to generate.
object	An object of class lifetable.
x	The attained age of subject $x$ . Default value is 0.
k	Number of periods within the year when it is possible death to happen. Default value is 1.
type	Either "Tx" for continuous future lifetime or "Kx" for curtate future lifetime

**Details**

Following relation holds for the future life time:  $T_x = K_x + 0.5$ .

**Value**

A numeric vector of n elements.

**Warning**

The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Note**

This function will probably will improved in the future.

**Author(s)**

Giorgio A. Spedicato

**References**

Actuarial Mathematics (Second Edition), 1997, by Bowers, N.L., Gerber, H.U., Hickman, J.C., Jones, D.A. and Nesbitt, C.J.

**See Also**

[lifetable](#), [exn](#)

**Examples**

```
##get 20000 random future lifetimes for the Soa life table at birth
data(soa08Act)
lifes=rLife(n=20000,object=soa08Act, x=0, type="Tx")
##check if the expected life at birth derived from the life table
##is statistically equal to the expected value of the sample
#
t.test(x=lifes, mu=exn(soa08Act, x=0, type="continuous"))
```

---

rLifeContingencies      *Function to generate samples from the life contingencies stochastic variables.*

---

### Description

This function returns a n-size sample from the underlying present value of benefits stochastic variable defined by a specific life contingencies insurance form.

### Usage

```
rLifeContingencies(n, lifecontingency, object, x, t,
i = object@interest, m=0, k = 1 , parallel=FALSE, payment="advance")
```

### Arguments

n	Size of sample
lifecontingency	A character string, either "Exn" or "Axn" or "axn" or "IAxn" or "DAxn".
object	An actuarialtable object.
x	Policyholder's age at issue time.
t	The length of the insurance. Must be specified according to the present value of benefits definition.
i	The interest rate, whose default value is the actuarialtable interest rate slot value.
m	Deferring period, default value is zero.
k	Fractional payment, default value is 1.
parallel	Uses the parallel computation facility.
payment	Payment type: "advance" default is the annuity due, otherwise annuity due.

### Details

This function is a wrapper for internal function that returns the present value of insured benefits.

### Value

A numeric vector.

### Warning

Before using this function, the unbiasedness of the sample drawn from the distribution shall be verified. The function is still in testing and for some classes of life contingencies biased. The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software. Currently  $k > 1$  computation are not supported yet.

**Note**

This function is a wrapper for many internal functions. It is called by all actuarial mathematics functions when value "ST" is provided to type parameter.

**Author(s)**

Giorgio Alfredo Spedicato.

**References**

x=x,lx=Ix,name="SOA2008"))
out<-rLifeContingencies(n=1000, lifecontingency="Axn",object=sofarAct,
x=40,t=getOmega(sofarAct)-40, i=sofarAct@interest,m=0)
APV=Axn(sofarAct,x=40)
#check if out distribution is unbiased
t.test(x=out, mu=APV)$p.value>0.05
```

---

rLifeContingenciesXyz *Function to return samples from lifecontingencies on multiple heads*

---

**Description**

This function returns samples from multiple heads life contingent insurances.

**Usage**

```
rLifeContingenciesXyz(n, lifecontingency, tablesList, x, t, i, m = 0,
k = 1, status = "joint", parallel = FALSE, payment = "advance")
```

**Arguments**

n	Sample size
lifecontingency	Either "Axyz" or "axyz"
tablesList	List of tables

x	Ages vector
t	Term
i	Interest rate
m	Deferral period
k	Frequency of payments
status	Either "joint" (default) or "last"
parallel	Use parallel computation
payment	Payment type: "advance" default is the annuity due, otherwise annuity immediate.

**Details**

This function should return samples from multiple life contingent insurances.

**Value**

A matrix of variates

**Warning**

The function is experimental and it its early stages. Samples are biased.

**Note**

A matrix is returned.

**Author(s)**

Giorgio Alfredo Spedicato, Kevin J. Owens.

SoAISTdata

*SoA illustrative service table*

---

**Description**

Bowers' book Illustrative Service Table

**Usage**

```
data(SoAISTdata)
```

**Format**

A data frame with 41 observations on the following 6 variables.

x Attained age  
lx Surviving subjects at the beginning of each age  
death Drop outs for death cause  
withdrawal Drop outs for withdrawal cause  
inability Drop outs for inability cause  
retirement Drop outs for retirement cause

**Details**

It is a data frame that can be used to create a multiple decrement table

**Source**

Optical recognized characters from below source with some few adjustments

**References**

Actuarial Mathematics (Second Edition), 1997, by Bowers, N.L., Gerber, H.U., Hickman, J.C., Jones, D.A. and Nesbitt, C.J.

**Examples**

```

tail(soalt)
```

---

$T_x$	<i>Number of person-years lived after exact age <math>x</math></i>
-------	--

---

**Description**

This function returns the number of years lived after exact age  $x$ .

**Usage**

```
Tx(object, x)
```

**Arguments**

object           A lifetable object

x                An integer representing the age for which the  $T_x$  value shall be returned.

**Details**

x shall be an integer value.

**Value**

A numeric value.

**Warning**

The function is provided as is, without any warranty regarding the accuracy of calculations. The author disclaims any liability for eventual losses arising from direct or indirect use of this software.

**Note**

The calculation is performed on all  $x$  where  $l_x > 0$ .
