

Package ‘marmap’

July 2, 2014

Type Package

Title Import, plot and analyze bathymetric and topographic data

Version 0.8

Date 2014-06-17

Author Eric Pante and Benoit Simon-Bouhet

Maintainer Eric Pante <pante.eric@gmail.com>

Depends R (>= 2.10)

Imports RSQLite, gdistance, geosphere, sp, raster, ncdf, plotrix,shape

Suggests maps, mapdata, lattice, mapproj

Description Import, plot and analyze bathymetric and topographic data

License GPL (>= 3)

NeedsCompilation no

add.nas	<i>Adds NAs to a vector</i>
---------	-----------------------------

Description

Internal function to add NAs to a vector (used in read.bathy and as.bathy)

Usage

```
add.nas(vec, pos.missing)
```

Arguments

vec	vector of data (in the context of marmap, depth/altitude values, ie 3rd column of xyz files)
pos.missing	vector, position of missing value in the future bathy object

Value

The function returns an updated vector containing both the original data and NAs at the positions imposed by argument `pos.missing`. The length of the resulting vector equals the sum of lengths of `vec` and `pos.missing`.

Author(s)

Benoit Simon-Bouhet

Examples

```
add.nas(vec=c("-100", "-200", "-500"), pos.missing=3)
```

aleutians

Bathymetric data for the Aleutians (Alaska)

Description

Bathymetric matrix of class `bathy` created from NOAA GEODAS data.

Usage

```
data(aleutians)
```

Details

Data imported from the NOAA GEODAS Grid Translator webpage (http://www.ngdc.noaa.gov/mgg/gdas/gd_designagrid.html) and transformed into an object of class `bathy` by `as.bathy`.

Value

A text file.

Author(s)

see http://www.ngdc.noaa.gov/mgg/gdas/gd_designagrid.html

# test plot.bathy
plot(aleutians, image = TRUE,
     bpal = list(c(0, max(aleutians), "grey"),
                 c(min(aleutians), 0, "darkblue", "lightblue")),
     land = TRUE, lwd = 0.1, axes = FALSE)
antimeridian.box(aleutians, 10)
```

antimeridian.box	<i>Adds a box to maps including antimeridian</i>
------------------	--

Description

Adds a box on maps including the antimeridian (180)

Usage

```
antimeridian.box(object, tick.spacing)
```

Arguments

object	matrix of class bathy
tick.spacing	spacing between tick marks (in degrees, default=20)

Value

The function adds a box and tick marks to an existing plot which contains the antimeridian line (180 degrees).

plot(aleutians,n=1,axes=FALSE)
antimeridian.box(aleutians, 10)
```

`as.bathy`*Convert to bathymetric data in an object of class bathy*

Description

Reads either an object of class `RasterLayer`, `SpatialGridDataFrame` or a three-column `data.frame` containing longitude (x), latitude (y) and depth (z) data and converts it to a matrix of class `bathy`.

Usage

```
as.bathy(x)
```

Arguments

`x` Object of `RasterLayer` or `SpatialGridDataFrame`, or a three-column `data.frame` with longitude (x), latitude (y) and depth (z) (no default)

Details

`x` can contain data downloaded from the NOAA GEODAS Grid Translator webpage (<http://www.ngdc.noaa.gov/mgg/gdas/gd>) in the form of an xyz table. The function `as.bathy` can also be used to transform objects of class `raster` (see package `raster`) and `SpatialGridDataFrame` (see package `sp`).

Value

The output of `as.bathy` is a matrix of class `bathy`, which dimensions and resolution are identical to the original object. The class `bathy` has its own methods for summarizing and plotting the data.

Author(s)

Benoit Simon-Bouhet

Examples

```
# load NW Atlantic data
data(nw.atlantic)

# use as.bathy
atl <- as.bathy(nw.atlantic)

# class "bathy"
class(atl)

# summarize data of class "bathy"
summary(atl)
```

as.raster

Convert bathymetric data to a raster layer

Description

Transforms an object of class bathy to a raster layer.

Usage

```
as.raster(bathy)
```

Arguments

bathy an object of class bathy

Details

as.raster transforms bathy objects into objects of class RasterLayer as defined in the raster package. All methods from the raster package are thus available for bathymetric data (e.g. rotations, projections...).

Value

An object of class RasterLayer with the same characteristics as the bathy object (same longitudinal and latitudinal ranges, same resolution).

Author(s)

Benoit Simon-Bouhet

[as.xyz](#), [as.bathy](#), [as.SpatialGridDataFrame](#)

Examples

```
# load Hawaii bathymetric data
data(hawaii)

# use as.raster
r.hawaii <- as.raster(hawaii)

# class "RasterLayer"
class(r.hawaii)

# Summaries
summary(hawaii)
summary(r.hawaii)

# structure of the RasterLayer object
str(r.hawaii)

## Not run:
# Plots
#require(raster)
plot(hawaii, image=TRUE, lwd=.2)
plot(r.hawaii)

## End(Not run)
```

as.SpatialGridDataFrame

Convert bathymetric data to a spatial grid

Description

Transforms an object of class bathy to a SpatialGridDataFrame object.

Usage

```
as.SpatialGridDataFrame(bathy)
```

Arguments

bathy an object of class bathy

Details

as.SpatialGridDataFrame transforms bathy objects into objects of class SpatialGridDataFrame as defined in the sp package. All methods from the sp package are thus available for bathymetric data (e.g. rotations, projections...).

Value

An object of class `SpatialGridDataFrame` with the same characteristics as the `bathy` object (same longitudinal and latitudinal ranges, same resolution).

Examples

```
# load Hawaii bathymetric data
data(hawaii)

# use as.SpatialGridDataFrame
sp.hawaii <- as.SpatialGridDataFrame(hawaii)

# Summaries
summary(hawaii)
summary(sp.hawaii)

# structure of the SpatialGridDataFrame object
str(sp.hawaii)

# Plots
plot(hawaii, image=TRUE, lwd=.2)
image(sp.hawaii)
```

as.xyz

Convert to xyz format

Description

Converts a matrix of class `bathy` into a three-column data.frame containing longitude, latitude and depth data.

Usage

```
as.xyz(bathy)
```

Arguments

`bathy` matrix of class `bathy`.

Details

The use of `as.bathy` and `as.xyz` allows to switch back and forth between the long format (`xyz`) and the wide format of class `bathy` suitable for plotting bathymetric maps, computing least cost distances, etc. `as.xyz` is especially useful for exporting `xyz` files when data are obtained using `subsetSQL`, i.e. bathymetric matrices of class `bathy`.

Value

Three-column data.frame with a format similar to `xyz` files downloaded from the NOAA GEODAS Grid Translator webpage (http://www.ngdc.noaa.gov/mgg/gdas/gd_designagrid.html). The first column contains longitude data, the second contains latitude data and the third contains depth/elevation data.

# use as.xyz
celt2 <- as.xyz(celt)
dim(celt2)
class(celt2)
summary(celt2)
```

celt

Bathymetric data for the North Est Atlantic

Description

Bathymetric matrix of class `bathy` created from NOAA GEODAS data.

Usage

```
data(celt)
```

Details

Data imported from the NOAA GEODAS Grid Translator webpage (http://www.ngdc.noaa.gov/mgg/gdas/gd_designagrid.html) and transformed into an object of class bathy by `as.bathy`.

Value

A text file.

# test plot.bathy
plot(celt, deep=-300, shallow=-50, step=25)
```

check.bathy

Sort bathymetric data matrix by increasing latitude and longitude

Description

Reads a bathymetric data matrix and orders its rows and columns by increasing latitude and longitude.

Usage

```
check.bathy(x)
```

Arguments

x a matrix

Details

check.bathy allows to sort rows and columns by increasing latitude and longitude, which is necessary for plotting with the function image (package graphics). check.bathy is used within the marmap functions read.bathy and as.bathy (it is also used in getNOAA.bathy through as.bathy).

Value

The output of check.bathy is an ordered matrix.

Examples

```
matrix(1:100, ncol=5, dimnames=list(20:1, c(3,2,4,1,5))) -> a
check.bathy(a)
```

col2alpha

Adds alpha transparency to a (vector of) color(s)

Description

Adds transparency to a color or a vector of colors by specifying one or several alpha values.

Usage

```
col2alpha(color, alpha = 0.5)
```

Arguments

color	a (vector of) color codes or names
alpha	a value (or vector of values) between 0 (full transparency) and 1 (no transparency).

Details

When the size of color and alpha vectors are different, alpha values are recycled.

Value

A (vector) of color code(s).

Author(s)

Benoit Simon-Bouhet

Examples

```
# Generate random data
dat <- rnorm(4000)

# plot with plain color for points
plot(dat,pch=19,col="red")

# Add some transparency to get a better idea of density
plot(dat,pch=19,col=col2alpha("red",.3))

# Same color for all points but with increasing alpha (decreasing transparency)
plot(dat,pch=19,col=col2alpha(rep("red",4000),seq(0,1,len=4000)))

# Two colors, same alpha
plot(dat,pch=19,col=col2alpha(rep(c("red","purple"),each=2000),.2))

# Four colors, gradient of transparency for each color
plot(dat,pch=19,col=col2alpha(rep(c("blue","purple","red","orange"),each=1000),seq(.1,.6,len=1000)))

# Alpha transparency applied to a gradient of colors
plot(dat,pch=19,col=col2alpha(rainbow(4000),.5))
```

collate.bathy

Collates two bathy matrices with data from either sides of the antimeridian

Description

Collates two bathy matrices, one with longitude 0 to 180 degrees East, and the other with longitude 0 to 180 degrees West

Usage

```
collate.bathy(east,west)
```

Arguments

east	matrix of class bathy with eastern data (West of antimeridian)
west	matrix of class bathy with western data (East of antimeridian)

Details

This function is meant to be used with `read.bathy()` or `readGEBCO.bathy()`, when data is downloaded from either sides of the antimeridian line (180 degrees longitude). If, for example, data is downloaded from GEBCO for longitudes of 170E-180 and 180-170W, `collate.bathy()` will create a single matrix of class `bathy` with a coordinate system going from 170 to 190 degrees longitude.

`getNOAA.bathy()` deals with data from both sides of the antimeridian and does not need further processing with `collate.bathy()`.

Value

A single matrix of class `bathy` that can be interpreted by `plot.bathy`. When plotting collated data (with longitudes 0 to 180 and 180 to 360 degrees), plots can be modified to display the conventional coordinate system (with longitudes 0 to 180 and -180 to 0 degrees) using function `antimeridian.box()`.

Examples

```
## faking two datasets using aleutians, for this example
## "a" and "b" simulate two datasets downloaded from GEBCO, for ex.
data(aleutians)
aleutians[1:181,] -> a ; "bathy" -> class(a)
aleutians[182:601,] -> b ; "bathy" -> class(b)
-(360-as.numeric(rownames(b))) -> rownames(b)

## check these objects with summary(): pay attention of the Longitudinal range
summary(aleutians)
summary(a)
summary(b)

## merge datasets:
collate.bathy(a,b) -> collated
summary(collated) # should be identical to summary(aleutians)
```

diag.bathy

Finds matrix diagonal for non-square matrices

Description

Finds either the values of the coordinates of the non-linear diagonal of non-square matrices.

Usage

```
diag.bathy(mat, coord=FALSE)
```

Arguments

mat	a data matrix
coord	whether of not to output the coordinates of the diagonal (default is FALSE)

Details

diag.bathy gets the values or coordinates from the first element of a matrix to its last elements. If the matrix is non-square, that is, its number of rows and columns differ, diag.bathy computes an approximate diagonal.

Value

A vector of diagonal values if coord is FALSE, or a table of diagonal coordinates if coord is TRUE

Author(s)

Eric Pante

matrix(1:25, 5, 5) -> a ; a
diag(a)
diag.bathy(a)

# a non-square matrix: diag.bathy does not behaves as diag
matrix(1:15, 3, 5) -> b ; b
diag(b)
diag.bathy(b)

# output the diagonal or its coordinates:
rownames(b) <- seq(32,35, length.out=3)
colnames(b) <- seq(-100,-95, length.out=5)
diag.bathy(b, coord=FALSE)
diag.bathy(b, coord=TRUE)
```

`florida`*Bathymetric data around Florida, USA*

Description

Bathymetric object of class `bathy` created from NOAA GEODAS data.

Usage

```
data(florida)
```

Details

Data imported from the NOAA GEODAS Grid Translator webpage (http://www.ngdc.noaa.gov/mgg/gdas/gd_designagrid.html) and transformed into an object of class `bathy` by `read.bathy`.

Value

A bathymetric object of class `bathy` with 539 rows and 659 columns.

Author(s)

see http://www.ngdc.noaa.gov/mgg/gdas/gd_designagrid.html

See Also

plot(florida, asp=1)
plot(florida, asp=1, image=TRUE, drawlabels=TRUE, land=TRUE, n=40)
```

get.area	<i>Get projected surface area</i>
----------	-----------------------------------

Description

Get projected surface area for specific depth layers

Usage

```
get.area(mat, level.inf, level.sup=0, xlim=NULL, ylim=NULL)
```

Arguments

mat	bathymetric data matrix of class bathy, imported using read.bathy (no default)
level.inf	lower depth limit for calculation of projected surface area (no default)
level.sup	upper depth limit for calculation of projected surface area (default is zero)
xlim	longitudinal range of the area of interest (default is NULL)
ylim	latitudinal range of the area of interest (default is NULL)

Details

get.area calculates the projected surface area of specific depth layers (e.g. upper bathyal, lower bathyal), the projected plane being the ocean surface. The resolution of get.area depends on the resolution of the input bathymetric data. xlim and ylim can be used to restrict the area of interest. Area calculation is based on areaPolygon of package geosphere (using an average Earth radius of 6,371 km).

Value

A list of four objects: the projected surface area in squared kilometers, a matrix with the cells used for calculating the projected surface area, the longitude and latitude of the matrix used for the calculations.

```

get.box

Get bathymetric information of a belt transect

Description

get.box gets depth information of a belt transect of width width around a transect defined by two points on a bathymetric map.

Usage

```
get.box(bathy,x1,x2,y1,y2,width,locator=FALSE,ratio=FALSE, ...)
```

Arguments

bathy	Bathymetric data matrix of class bathy.
x1	Numeric. Start longitude of the transect. Requested when locator=FALSE.
x2	Numeric. Stop longitude of the transect. Requested when locator=FALSE.
y1	Numeric. Start latitude of the transect. Requested when locator=FALSE.
y2	Numeric. Stop latitude of the transect. Requested when locator=FALSE.
width	Numeric. Width of the belt transect in degrees.
locator	Logical. Whether to choose transect bounds interactively with a map or not. When FALSE (default), a bathymetric map (plot.bathy(bathy, image=TRUE)) is automatically plotted and the position of the belt transect is added.
ratio	Logical. Should aspect ratio for the wireframe plotting function (package lattice) be computed (default is FALSE).
...	Other arguments to be passed to locator and lines to specify the characteristics of the points and lines to draw on the bathymetric map for both the transect and the bounding box of belt transect.

Details

get.box allows the user to get depth data for a rectangle area of the map around an approximate linear transect (belt transect). Both the position and size of the belt transect are user defined. The position of the transect can be specified either by inputting start and stop coordinates, or by clicking on a map created with plot.bathy. In its interactive mode, this function uses the locator function (graphics package) to retrieve and plot the coordinates of the selected transect. The argument width allows the user to specify the width of the belt transect in degrees.

Value

A matrix containing depth values for the belt transect. rownames indicate the kilometric distance from the start of the transect and colnames indicate the distance from the central transect in degrees. If ratio=TRUE, a list of two elements: depth, a matrix containing depth values for the belt transect similar to the description above and ratios a vector of length two specifying the ratio between (i) the width and length of the belt transect and (ii) the depth range and the length of the belt transect. These ratios can be used by the function wireframe to produce realistic 3D bathymetric plots of the selected belt transect.

Author(s)

Benoit Simon-Bouhet and Eric Pante

[plot.bathy](#), [get.transect](#), [get.depth](#)

Examples

```
# load and plot bathymetry
data(hawaii)
plot(hawaii,im=TRUE)

# get the depth matrix for a belt transect
depth <- get.box(hawaii,x1=-157,y1=20,x2=-155.5,y2=21,width=0.5,col=2)

# plotting a 3D bathymetric map of the belt transect
require(lattice)
wireframe(depth,shade=TRUE)

# get the depth matrix for a belt transect with realistic aspect ratios
depth <- get.box(hawaii,x1=-157,y1=20,x2=-155.5,y2=21,width=0.5,col=2,ratio=TRUE)

# plotting a 3D bathymetric map of the belt transect with realistic aspect ratios
require(lattice)
wireframe(depth[[1]],shade=TRUE,aspect=depth[[2]])
```

get.depth

Get depth data by clicking on a map

Description

Outputs depth information based on points selected by clicking on a map

Usage

```
get.depth(mat, x, y=NULL, locator=TRUE, distance=FALSE, ...)
```

Arguments

mat	Bathymetric data matrix of class bathy, as imported with read.bathy.
x	Either a list of two elements (numeric vectors of longitude and latitude), a 2-column matrix or data.frame of longitudes and latitudes, or a numeric vector of longitudes.
y	Either NULL (default) or a numerical vector of latitudes. Ignored if x is not a numeric vector.
locator	Logical. Whether to choose data points interactively with a map or not. If TRUE (default), a bathymetric map must have been plotted and both x and y are both ignored.
distance	whether to compute the haversine distance (in km) from the first data point on (default is FALSE). Only available when at least two points are provided.
...	Further arguments to be passed to locator when the interactive mode is used (locator=TRUE).

Details

get.depth allows the user to get depth data by clicking on a map created with plot.bathy or by providing coordinates of points of interest. This function uses the locator function (graphics package); after creating a map with plot.bathy, the user can click on the map once or several times (if locator=TRUE), press the Escape button, and get the depth of those locations in a three-column data.frame (longitude, latitude and depth). Alternatively, when locator=FALSE, the user can submit a list of longitudes and latitudes, a two-column matrix or data.frame of longitudes and latitudes (as input for x), or one vector of longitudes (x) and one vector of latitudes (y). The non-interactive mode is well suited to get depth information for each point provided by GPS tracking devices. While [get.transect](#) gets every single depth value available in the bathymetric matrix between two points along a user-defined transect, get.depth only provides depth data for the specific points provided as input by the user.

Value

A data.frame with at least, longitude, latitude and depth with one line for each point of interest. If distance=TRUE, a fourth column containing the kilometeric distance from the first point is added.

plot(atl, lwd=.5)
points(lon,lat,pch=19,col=2)

# Use get.depth to get the depth for each point
get.depth(atl, x=lon, y=lat, locator=FALSE)

# alternatively once the map is plotted, use the interactive mode:
## Not run:
get.depth(atl, locator=TRUE, pch=19, col=3)

## End(Not run)
# click several times and press Escape

```

get.sample

Get sample data by clicking on a map

Description

Outputs sample information based on points selected by clicking on a map

Usage

```
get.sample(mat, sample, col.lon, col.lat, ...)
```

Arguments

mat	bathymetric data matrix of class bathy, imported using read.bathy (no default)
sample	data.frame containing sampling information (at least longitude and latitude) (no default)
col.lon	column number of data frame sample containing longitude information (no default)
col.lat	column number of data frame sample containing latitude information (no default)
...	further arguments to be passed to <code>rect</code> for drawing a box around the selected area

Details

get.sample allows the user to get sample data by clicking on a map created with plot.bathy. This function uses the locator function (graphics package). After creating a map with plot.bathy, the user can click twice on the map to delimit an area (for example, lower left and upper right corners of a rectangular area of interest), and get a dataframe corresponding to the sample points present within the selected area.

Value

a dataframe of the elements of sample present within the area selected

Warning

clicking once or more than twice on the map will return a warning message: "Please choose two points from the map"

# click twice

## End(Not run)
```

get.transect

Compute approximate cross section along a depth transect

Description

Compute the depth along a linear transect which bounds are specified by the user.

Usage

```
get.transect(mat, x1, y1, x2, y2, locator=FALSE, distance=FALSE, ...)
```

Arguments

<code>mat</code>	bathymetric data matrix of class <code>bathy</code> , imported using <code>read.bathy</code> (no default)
<code>x1</code>	start longitude of the transect (no default)
<code>x2</code>	stop longitude of the transect (no default)
<code>y1</code>	start latitude of the transect (no default)
<code>y2</code>	stop latitude of the transect (no default)
<code>locator</code>	whether to use locator to choose transect bounds interactively with a map (default is <code>FALSE</code>)
<code>distance</code>	whether to compute the haversine distance (in km) from the start of the transect, along the transect (default is <code>FALSE</code>)
<code>...</code>	other arguments to be passed to <code>locator()</code> to specify the characteristics of the points and lines to draw on the bathymetric map when <code>locator=TRUE</code> .

Details

`get.transect` allows the user to compute an approximate linear depth cross section either by inputting start and stop coordinates, or by clicking on a map created with `plot.bathy`. In its interactive mode, this function uses the `locator` function (`graphics` package); after creating a map with `plot.bathy`, the user can click twice to delimit the bound of the transect of interest (for example, lower left and upper right corners of a rectangular area of interest), press `Escape`, and get a table with the transect information.

Value

A table with, at least, longitude, latitude and depth along the transect, and if specified (`distance=TRUE`), the distance in kilometers from the start of the transect. The number of elements in the resulting table depends on the resolution of the `bathy` object.

Warning

Clicking once or more than twice on the map will return a warning message: "Please choose only two points from the map". Manually entering coordinates that are outside the geographical range of the input `bathy` matrix will return a warning message.

Note

The `distance` option of `get.transect` is calculated based on the haversine formula for getting the great circle distance (takes into account the curvature of the Earth). `get.transect` uses an internal function called `diag.bathy` that extracts the approximate diagonal of a matrix, when that matrix has uneven dimensions (different numbers of columns and rows).

```

getNOAA.bathy

Import bathymetric data from the NOAA server

Description

Imports bathymetric data from the NOAA server, given coordinate bounds and resolution.

Usage

```
getNOAA.bathy(lon1,lon2,lat1,lat2, resolution = 4, keep=FALSE, antimeridian=FALSE)
```

Arguments

lon1	first longitude of the area for which bathymetric data will be downloaded
lon2	second longitude of the area for which bathymetric data will be downloaded
lat1	first latitude of the area for which bathymetric data will be downloaded
lat2	second latitude of the area for which bathymetric data will be downloaded
resolution	resolution of the grid, in minutes (default is 4)

keep	whether to write the data downloaded from NOAA into a file (default is FALSE)
antimeridian	whether the area should include the antimeridian (longitude 180 or -180). See details.

Details

getNOAA.bathy queries the ETOPO1 database hosted on the NOAA website, given the coordinates of the area of interest and desired resolution. Users have the option of directly writing the downloaded data into a file (keep=TRUE argument ; see below). If an identical query is performed (i.e. using identical lat-long and resolution), getNOAA.bathy will load data from the file previously written to the disk instead of querying the NOAA database. This behavior should be used preferentially (1) to reduce the number of unnecessary queries to the NOAA website, and (2) to reduce data load time. If the user wants to make multiple, identical queries to the NOAA website without loading the data written to disk, the data file name must be modified by the user. Alternatively, the data file can be moved outside of the present working directory.

getNOAA.bathy allows users to download bathymetric data in the antimeridian region when antimeridian=TRUE. The antimeridian is the 180th meridian and is located about in the middle of the Pacific Ocean, east of New Zealand and Fidji, west of Hawaii and Tonga. For a given pair of longitude values, e.g. -150 (150 degrees West) and 150 (degrees East), you have the possibility to get data for 2 distinct regions: the area centered on the antimeridian (60 degrees wide, when antimeridian=TRUE) or the area centered on the prime meridian (300 degrees wide, when antimeridian=FALSE). It is recommended to use keep=TRUE in combination with antimeridian=TRUE since gathering data for an area around the antimeridian requires two distinct queries to NOAA servers.

Value

The output of getNOAA.bathy is a matrix of class bathy, which dimensions depends on the resolution of the grid uploaded from the NOAA server. The class bathy has its own methods for summarizing and plotting the data. If keep=TRUE, a csv file containing the downloaded data is produced. This file is named using the following format: 'marmap_coord_COORDINATES_res_RESOLUTION.csv' (COORDINATES separated by semicolons, and the RESOLUTION in degrees).

hawaii

Bathymetric data for Hawaii, USA

Description

Bathymetric object of class `bathy` created from NOAA GEODAS data and arbitrary locations around the main Hawaiian islands.

Usage

```
data(hawaii)
data(hawaii.sites)
```

Details

`hawaii` contains data imported from the NOAA GEODAS Grid Translator webpage (http://www.ngdc.noaa.gov/mgg/gdas/gd_designagrid.html) and transformed into an object of class `bathy` by `read.bathy`. `hawaii.sites` is a 2-columns `data.frame` containing longitude and latitude of 6 locations spread at sea around Hawaii.

Value

`hawaii`: a bathymetric object of class `bathy` with 539 rows and 659 columns. `hawaii.sites`: `data.frame` (6 rows, 2 columns)

lc.dist

Computes least cost distances between two or more locations

Description

Computes least cost distances between two or more locations

Usage

```
lc.dist(trans,loc,res=c("dist","path"))
```

Arguments

trans	transition object as computed by trans.mat
loc	A two-columns matrix or data.frame containing latitude and longitude for 2 or more locations.
res	either "dist" or "path". See details.

Details

lc.dist computes least cost distances between 2 or more locations. This function relies on the package `gdistance` (van Etten, 2011. <http://CRAN.R-project.org/package=gdistance>) and on the `trans.mat` function to define a range of depths where the paths are possible.

Value

Results can be presented either as a kilometric distance matrix between all possible pairs of locations (argument `res="dist"`) or as a list of paths (i.e. 2-columns matrices of routes) between pairs of locations (`res="path"`).

metallo

Coral sampling information from the North West Atlantic

Description

Coral sampling data from Thoma et al 2009 (MEPS)

Usage

```
data(nw.atlantic)
```

Details

Sampling locations (longitude, latitude, depth in meters) for the deep-sea octocoral species *Metallogorgia melanotrichos* (see Thoma et al 2009 for details, including cruise information)

Value

A 3-column data frame

References

Thoma, J. N., E. Pante, M. R. Brugler, and S. C. France. 2009. Deep-sea octocorals and antipatharians show no evidence of seamount-scale endemism in the NW Atlantic. *Marine Ecology Progress Series* 397:25-35. <http://www.int-res.com/articles/theme/m397p025.pdf>

nw.atlantic

Bathymetric data for the North West Atlantic

Description

Data imported from the NOAA GEODAS server

Usage

```
data(nw.atlantic)
```

Details

Data imported from the NOAA GEODAS Grid Translator webpage (http://www.ngdc.noaa.gov/mgg/gdas/gd_designagrid.html). To prepare data from NOAA, fill the custom grid form, and choose "XYZ (lon,lat,depth)" as the "Output Grid Format", "No Header" as the "Output Grid Header", and either of the space, tab or comma as the column delimiter (either can be used, but "comma" is the default import format of read.bathy). Choose "omit empty grid cells" to reduce memory usage.

Value

A three-columns data.frame containing longitude, latitude and depth/elevation data.

```

palette.bathy

Build a bathymetry- and/or topography-constrained color palette

Description

Build a constrained color palette based on depth / altitude bounds and given colors.

Usage

```
palette.bathy(mat, layers, land=FALSE, default.col="white")
```

Arguments

mat	a matrix of bathymetric data, class bathy not required.
layers	a list of depth bounds and colors (see below)
land	logical. Whether to consider land or not (default is FALSE)
default.col	a color for the area of the matrix not bracketed by the list supplied to layers

Details

palette.bathy allows the production of color palettes for specified bathymetric and/or topographic layers. The layers argument must be a list of vectors. Each vector corresponds to a bathymetry/topography layer (for example, one layer for bathymetry and one layer for topography). The first and second elements of the vector are the minimum and maximum bathymetry/topography, respectively. The other elements of the vector (3, onward) correspond to colors (see example below). palette.bathy is called internally by plot.bathy when the image argument is set to TRUE.

Value

A vector of colors which size depends on the depth / altitude range of the bathy matrix.

Author(s)

Eric Pante and Benoit Simon-Bouhet

```

path.profile *Geographic coordinates, kilometric distance and depth along a path*

Description

Computes and plots the depth/altitude along a transect or path

Usage

```
path.profile(path,bathy,plot=FALSE, ...)
```

Arguments

path	2-columns matrix of longitude and latitude as obtained from <code>lc.dist</code> with argument <code>dist=TRUE</code> .
bathy	bathymetric data matrix of class <code>bathy</code> .
plot	logical. Should the depth profile be plotted?
...	when <code>plot=TRUE</code> , other arguments to be passed to <code>plotProfile</code> , such as graphical parameters (see par and plotProfile).

Value

a four-columns matrix containing longitude, latitude, kilometric distance from the start of a route and depth for a set of points along a route. Optionally (i.e. when `plot=TRUE`) a bivariate plot of depth against the kilometric distance from the starting point of a transect or least cost path.

plot.bathy

Plotting bathymetric data

Description

Plots contour map from bathymetric data matrix of class bathy

Usage

```

## S3 method for class 'bathy'
plot(x, image=FALSE, bpal=NULL, land=FALSE,
     deepest.isobath, shallowest.isobath, step, n=20,
     lwd=1, lty=1, col="black", default.col="white", drawlabels = FALSE,
     xlab="Longitude", ylab="Latitude", asp=1, ...)

```

Arguments

x	bathymetric data matrix of class bathy, imported using read.bathy
image	whether or not to color depth layers (default is FALSE)
bpal	if image is TRUE, either NULL (default: a simple blue color palette is used), a vector of colors, or a list of depth bounds and colors (see below)
land	whether or not to use topographic data that may be available in the bathy dataset (default is FALSE)
deepest.isobath	deepest isobath(s) to plot
shallowest.isobath	shallowest isobath(s) to plot
step	distance(s) between two isobaths
n	if the user does not specify the range within which isobaths should be plotted, about n isobaths are automatically plotted within the depth range of the bathy matrix (default is 20).
lwd	isobath line(s) width (default is 1)
lty	isobath line type(s) (default is 1)

<code>col</code>	isobath line color(s) (default is black)
<code>default.col</code>	if <code>image</code> is TRUE, a color for the area of the matrix not bracketed by the list supplied to <code>bpal</code> (see below; default is white)
<code>drawlabels</code>	whether or not to plot isobath depth as a label (default is FALSE); may contain several elements
<code>xlab</code>	label for the x axis of the plot
<code>ylab</code>	label for the y axis of the plot
<code>asp</code>	numeric, giving the aspect ratio y/x of the plot. See plot.window
<code>...</code>	Other arguments to be passed either to <code>countour</code> (default) or to <code>image</code> when argument <code>image=TRUE</code> .

Details

`plot.bathy` uses the base `contour` and `image` functions. If a vector of isobath characteristics is provided, different types of isobaths can be added to the same plot using a single call of `plot.bathy` (see examples)

If `image=TRUE`, the user has three choices for colors: (1) `bpal` can be set to NULL, in which case a default blue color palette is generated; (2) colors can be user-defined as in example 4, in which case the palette can be generated with function `colorRampPalette` (colors are then supplied as a vector to `plot.bathy`); (3) colors can be constrained to bathymetry- and/or topography. In this last case, a list of vectors is supplied to `plot.bathy` (example 7): each vector corresponds to a bathymetry/topography layer (for example, one layer for bathymetry and one layer for topography). The first and second elements of the vector are the minimum and maximum bathymetry/topography, respectively. The other elements of the vector (3, onward) correspond to colors (see example 7).

Value

a bathymetric map with isobaths

Note

`plot.bathy` uses a matrix of class `bathy`, and can therefore be substituted for `plot`.

Examples

```

# load NW Atlantic data and convert to class bathy
data(nw.atlantic)
atl <- as.bathy(nw.atlantic)

## Example 1: a simple marine chart
plot(atl) # without specifying any isobath parameters
plot(atl, n=5, drawlabels=TRUE) # with about 5 isobaths
plot(atl, deep=-8000, shallow=0, step=1000) # with isobath parameters

## Example 2: taking advantage of multiple types of isobaths
plot(atl, deep=c(-8000,-2000,0), shallow=c(-2000,-100,0), step=c(1000,100,0),
     lwd=c(0.5,0.5,1),lty=c(1,1,1),col=c("grey80","red", "blue"),
     drawlabels=c(FALSE,FALSE,FALSE) )

## Example 3: plotting a colored map with the default color palette
plot(atl, image=TRUE, deep=c(-8000,0), shallow=c(-1000,0), step=c(1000,0),
     lwd=c(0.5,1), lty=c(1,1), col=c("grey","black"), drawlabels=c(FALSE,FALSE))

## Example 4: make a pretty custom color ramp
colorRampPalette(c("purple","lightblue","cadetblue2","cadetblue1","white")) -> blues

plot(atl, image=TRUE, bpal=blues(100), deep=c(-6500,0), shallow=c(-50,0), step=c(500,0),
     lwd=c(0.3,1), lty=c(1,1), col=c("black","black"), drawlabels=c(FALSE,FALSE))

scaleBathy(atl, deg=3, x="bottomleft", inset=5)

## Example 5: add points corresponding to sampling locations
##           point colors correspond to the sampling depth
par(mai=c(1,1,1,1.5))
plot(atl, deep=c(-4500,0), shallow=c(-50,0), step=c(500,0),
     lwd=c(0.3,1), lty=c(1,1), col=c("black","black"), drawlabels=c(FALSE,FALSE))

# add a title to the plot
title(main="Distribution of coral samples\non the New England and Corner Rise seamounts")
# add a scale
scaleBathy(atl, deg=3, x="bottomleft", inset=5)

# add a geographical reference on the coast:
points(-71.064,42.358, pch=19)
text(-71.064,42.358,"Boston", adj=c(1.2,0))

# prepare colors for the sampling locations:
data(metallo) ## see dataset metallo
max(metallo$depth, na.rm=TRUE) -> mx
colorRampPalette(c("white","lightyellow","lightgreen","blue","lightblue1","purple")) -> ramp
blues <- ramp(max(metallo$depth))

# plot sampling locations:
points(metallo, col="black", bg=blues[metallo$depth], pch=21,cex=1.5)
library(shape)
colorlegend(zlim=c(-mx,0), col=rev(blues), main="depth (m)",posx=c(0.85,0.88))

```

```
## Example 6: use packages maps and mapdata in combination with marmap
# use maps and mapdata to plot the coast
library(maps)
library(mapdata)
map('worldHires',xlim=c(-75,-46),ylim=c(32,44), fill=TRUE, col="grey")
box();axis(1);axis(2)

# add bathymetric data from 'bathy' data
plot(atl, add=TRUE, lwd=.3, deep=-4500, shallow=-10, step=500,
drawlabel=FALSE, col="grey50")

## Example 7: provide a list of depths and colors to argument bpal to finely tune palette
# check out ?palette.bathy to see details on how the palette is handled

# creating depth-constrained palette for the ocean only
plot(atl, land = FALSE, n = 10, lwd = 0.5, image = TRUE,
      bpal = list(c(min(atl), 0, "purple", "blue", "lightblue")),
      default.col = "gray")

# creating depth-constrained palette for 3 ocean "layers"
plot(atl, land = FALSE, n = 10, lwd = 0.7, image = TRUE,
      bpal = list(c(min(atl), -3000, "purple", "blue", "grey"),
                  c(-3000, -150, "white"),
                  c(-150, 0, "yellow", "green", "brown")),
      default.col = "grey")

# creating depth-constrained palette for land and ocean
plot(atl, land = TRUE, n = 10, lwd = 0.7, image = TRUE,
      bpal = list(c(min(atl), 0, "purple", "blue", "lightblue"),
                  c(0, max(atl), "gray90", "gray10")))
```

plotProfile

Plotting bathymetric data along a transect or path

Description

Plots the depth/altitude along a transect or path

Usage

```
plotProfile(profile,shadow=TRUE,xlim,ylim,col.sea,col.bottom,xlab,ylab, ...)
```

Arguments

profile	4-columns matrix obtained from get.transect with argument dist=TRUE, or from path.profile.
shadow	logical. Should the depth profile cast a shadow over the plot background?

xlim, ylim	numeric vectors of length 2, giving the x and y coordinates ranges. If unspecified, xlim values are based on the length of the transect or path and ylim values are based on the depth range of the bathymetric matrix bathy.
col.sea	color for the sea area of the plot. Defaults to <code>rgb(130/255,180/255,212/255)</code>
col.bottom	color for the bottom area of the plot. Defaults to <code>rgb(198/255,184/255,151/255)</code>
xlab, ylab	titles for the x and y axes. If unspecified, <code>xlab="Distance from start of transect (km)"</code> and <code>ylab="Depth (m)"</code>
...	arguments to be passed to methods, such as graphical parameters (see <code>par</code>)

Value

a bivariate plot of depth against the kilometric distance from the starting point of a transect or least cost path.

Note

`path.profile` with argument `plot` set to `TRUE` plots depth profiles with default values for all arguments of `plotProfile`.

read.bathy

Read bathymetric data in XYZ format

Description

Reads a three-column table containing longitude (x), latitude (y) and depth (z) data.

Usage

```
read.bathy(xyz, header = FALSE, sep = ",")
```

Arguments

xyz	three-column table with longitude (x), latitude (y) and depth (z) (no default)
header	whether this table has a row of column names (default = FALSE)
sep	character separating columns, (default=",")

Details

Allows direct import of data from the NOAA GEODAS Grid Translator webpage (http://www.ngdc.noaa.gov/mgg/gdas/gd_designagrid.html). To prepare data from NOAA, fill the custom grid form, and choose "XYZ (lon,lat,depth)" as the "Output Grid Format", "No Header" as the "Output Grid Header", and either of the space, tab or comma as the column delimiter (either can be used, but "comma" is the default import format of read.bathy). Choose "omit empty grid cells" to reduce memory usage.

Value

The output of read.bathy is a matrix of class bathy, which dimensions depends on the resolution of the grid uploaded from the NOAA GEODAS server (Grid Cell Size). The class bathy has its own methods for summarizing and plotting the data.

```

readGEBCO.bathy	<i>Read bathymetric data from a GEBCO file</i>
-----------------	--

Description

Imports 30-sec and 1-min bathymetric data from a .nc file downloaded on the GEBCO website.

Usage

```
readGEBCO.bathy(file, db = "GEBCO_1min", resolution = 1)
```

Arguments

file	name of the .nc file
db	type of GEBCO database queried, either GEBCO_1min or GEBCO_08 (default is GEBCO_1min)
resolution	resolution of the grid, in units of the selected database (default is 1; see details)

Details

readGEBCO.bathy reads a 30 arcseconds or 1 arcminute bathymetry file downloaded from the GEBCO (General Bathymetric Chart of the Oceans) website (British Oceanographic Data Center). The website allows the download of bathymetric data in the netCDF format. readGEBCO.bathy uses the ncdf package to load the data into R, and parses it into an object of class bathy.

The argument db specifies whether data was downloaded from the 30 arcseconds database (GEBCO_08) or the 1 arcminute database (GEBCO_1min, the default). A third database type, GEBCO_08 SID, is available from the website. This database includes a source identifier specifying which grid cells have depth information based on soundings ; it does not include bathymetry or topography data. readGEBCO.bathy can read this type of database with db = "GEBCO_08", and only the SID information will be included in the object of class bathy. Therefore, to display a map with both the bathymetry and the SID information, you will have to download both datasets from GEBCO, and import and plot both independently.

The argument resolution specifies the resolution of the object of class bathy. Because the resolution of GEBCO data is rather fine, we offer the possibility of downsizing the dataset with resolution. resolution is in units of the selected database: in "GEBCO_1min", resolution is in minutes; in "GEBCO_08", resolution is in 30 arcseconds (that is, resolution = 3 corresponds to 3x30sec, or 1.5 arcminute).

About warnings: sometimes, a GEBCO-generated nc file will have fewer z values than expected given the dimension queried on the server. For example, if we asked for a region including 281 latitude values and 391 longitude values, there should be 281x391=109871 cells, but might in reality get fewer cells, for example 280x390=109200 cells. We think that this is due to the way the GEBCO server extracts the data based on your query. To deal with it, we remove the last latitude and longitude values of the matrix so that the number of cells and the number of latitude x longitude values match exactly. When this happens, readGEBCO.bathy sends a warning message to let you know of the situation.

Value

The output of readGEBCO.bathy is a matrix of class bathy, which dimensions depends on the resolution specified (one-minute, the original GEBCO resolution, is the default). The class bathy has its own methods for summarizing and plotting the data.

as.numeric(colnames(sid)) -> y.sid
contour(x.sid, y.sid, sid, drawlabels=FALSE, lwd=.1, add=TRUE) # SID

## End(Not run)
```

scaleBathy

Adds a scale to a map

Description

Uses geographic information from object of class bathy to calculate and plot a scale in kilometer.

Usage

```
scaleBathy(mat, deg=1, x="bottomleft", y=NULL, inset=10, ...)
```

Arguments

mat	bathymetric data matrix of class bathy, imported using read.bathy
deg	the number of degrees of longitudes to convert into kilometers (default is 1)
x, y	the coordinates used to plot the scale on the map (see Details)
inset	when x is a keyword (e.g. "bottomleft"), inset is a percentage of the plotting space controlling the relative position of the plotted scale (see Examples)
...	further arguments to be passed to text

Details

scaleBathy is a simple utility to add a scale to the lower left corner of a bathy plot. The distance in kilometers between two points separated by 1 degree longitude is calculated based on the minimum latitude of the bathy object used to plot the map. Option deg allows the user to plot the distance separating more than one degree (default is one).

The plotting coordinates x and y either correspond to two points on the map (i.e. longitude and latitude of the point where the scale should be plotted), or correspond to a keyword (set with x, y being set to NULL) from the list "bottomright", "bottomleft", "topright", "topleft". When a keyword is used, the option inset controls how far the scale will be from the edges of the plot.

Value

a scale added to the active graphical device

Note

The calculation formula is from function map.scale of package maps. 6372.798 km is used as the Earth radius.

space.pies	<i>Automatic placement of piecharts on maps</i>
------------	---

Description

Attempts to automatically place piecharts on maps, avoiding overlap. Work in progress...

Usage

```
space.pies(x, y, pie.slices, pie.colors=NULL, pie.radius=1, pie.space=5,
           link=TRUE, seg.lwd=1, seg.col=1, seg.lty=1, coord=NULL)
```

Arguments

x	the longitude of the anchor point for the piechart
y	the latitude of the anchor point for the piechart
pie.slices	a table with the counts to draw pies (col: pie categories, or slices; rows: sites on the map)
pie.colors	a table with the colors to draw pies (col: pie categories, or slices; rows: sites on the map)
pie.radius	size of the piechart
pie.space	factor of spacing between the anchor and the pie (the larger, the farther the pie from the anchor)
link	logical; whether to add a segment to link pie and anchor
seg.lwd	the line width of the link
seg.col	the line color of the link
seg.lty	the line type of the link
coord	when coord = NULL (default), placement is automatic. Otherwise, a 2-col table of lon/lat for pies.

Details

space.pies tries to position piecharts on a map while avoiding overlap between them. The function heavily relies on two other functions. floating.pie from package plotrix is used to draw individual piecharts. floating.pie treats one pie at a time; space.pies can handle one or multiple pies by looping floating.pie. pointLabels from package maptools was modified to find the best placement for the pies, given their size and distance from their anchor point. pointLabels was originally meant to automatically place text labels, not objects; the modified version contained in space.pies uses the coordinates chosen by pointLabels for text. The algorithm used is simulating annealing (SANN). You can get a different result each time you run space.pies, because pointLabel finds one good solution out of many. If you are not satisfied by the solution, you can try running the function again.

The argument coord allows to choose between the automatic placement outlined above, and a user-defined list of longitudes and latitudes (in a two-column table format) for plotting the piecharts.

Anchor point: spatial location of the data corresponding to the piechart (e.g. a sampling point).

Value

Piechart(s) added to a plot.

subsetBathy

Creates bathy objects from larger bathy objects

Description

Generates rectangular or non rectangular bathy objects by extracting bathymetric data from larger bathy objects.

Usage

```
subsetBathy(mat, x, y=NULL, locator=TRUE, ...)
```

Arguments

mat	Bathymetric data matrix of class bathy, as imported with read.bathy.
x	Either a list of two elements (numeric vectors of longitude and latitude), a 2-column matrix or data.frame of longitudes and latitudes, or a numeric vector of longitudes.
y	Either NULL (default) or a numerical vector of latitudes. Ignored if x is not a numeric vector.
locator	Logical. Whether to choose data points interactively with a map or not. If TRUE (default), a bathymetric map must have been plotted and both x and y are both ignored.
...	Further arguments to be passed to locator when the interactive mode is used (locator=TRUE).

Details

subsetBathy allows the user to generate new bathy objects by extracting data from larger bathy objects. The extraction of bathymetric data can be done interactively by clicking on a bathymetric map, or by providing longitudes and latitudes for the boundaries for the new bathy object. If two data points are provided, a rectangular area is selected. If more than two points are provided, a polygon is defined by linking the points and the bathymetric data is extracted within the polygon only. subsetBathy relies on the point.in.polygon function from package sp to identify which points of the initial bathy matrix lie within the boundaries of the user-defined polygon.

Value

A matrix of class bathy.

Examples

```
# load aleutians dataset
data(aleutians)

# create vectors of latitude and longitude to define the boundary of a polygon
lon <- c(188.56, 189.71, 191, 193.18, 196.18, 196.32, 196.32, 194.34, 188.83)
lat <- c(54.33, 55.88, 56.06, 55.85, 55.23, 54.19, 52.01, 50.52, 51.71)

# plot the initial bathy and overlay the polygon
plot(aleutians, image=TRUE, land=TRUE, lwd=.2)
polygon(lon,lat)

# Use of subsetBathy to extract the new bathy object
zoomed <- subsetBathy(aleutians, x=lon, y=lat, locator=FALSE)

# plot the new bathy object
dev.new() ; plot(zoomed, land=TRUE, image=TRUE, lwd=.2)

# alternatively once the map is plotted, use the interactive mode:
## Not run:
plot(aleutians, image=TRUE, land=TRUE, lwd=.2)
zoomed2 <- subsetBathy(aleutians, pch=19, col=3)
dev.new() ; plot(zoomed2, land=TRUE, image=TRUE, lwd=.2)

## End(Not run)
# click several times and press Escape
```

subsetSQL

Creating and querying local SQL database for bathymetric data

Description

subsetSQL queries the local SQL database created with setSQL to extract smaller data subsets.

Usage

```
setSQL(bathy, sep="\t", header=TRUE)
subsetSQL(min_lon, max_lon, min_lat, max_lat)
```

Arguments

bathy	A text file containing a three-column table with longitude (x), latitude (y) and depth (z) (no default)
sep	character separating columns
header	whether this table has a row of column names (default = TRUE)
min_lon	minimum longitude of the data to be extracted from the local SQL database
max_lon	maximum longitude of the data to be extracted from the local SQL database
min_lat	minimum latitude of the data to be extracted from the local SQL database
max_lat	maximum latitude of the data to be extracted from the local SQL database

Details

Functions `setSQL` and `subsetSQL` were built to work together. `setSQL` builds an SQL database and saves it on disk. `subsetSQL` queries that local database and the fields `min_lon`, `max_lon`, etc, are used to extract a subset of the database. The functions were built as two entities so that multiple queries can be done multiple times, without re-building the database each time. These functions were designed to access the very large (>5Go) ETOPO1 file that can be downloaded from the NOAA website (<http://www.ngdc.noaa.gov/mgg/global/global.html>)

Value

`setSQL` returns TRUE if the database was successfully created. `subsetSQL` returns a matrix of class `bathy` that can directly be used with `plot.bathy`.

Note

There must be no database file called `bathy_db` in the working directory prior to running `setSQL`.

Examples

```

# load NW Atlantic data
data(nw.atlantic)

# write example file to disk
write.table(nw.atlantic, "NW_Atlantic.csv", sep=",", quote=FALSE, row.names=FALSE)

## Not run:
# prepare SQL database
setSQL(bathy="NW_Atlantic.csv", sep=",")

# uses data from the newly-created SQL database:
subsetSQL(min_lon=-70,max_lon=-50,
          min_lat=35, max_lat=41) -> test

# visualize the results (of class bathy)
summary(test)

# remove temporary database and CSV files
system("rm bathy_db") # remove file, for unix-like systems
system("rm NW_Atlantic.csv") # remove file, for unix-like systems

## End(Not run)

```

summary.bathy

Summary of bathymetric data of class bathy

Description

Summary of bathymetric data of class bathy. Provides geographic bounds and resolution (in minutes) of the dataset, statistics on depth data, and a preview of the bathymetric matrix.

Usage

```

## S3 method for class 'bathy'
summary(object, ...)

```

Arguments

object object of class bathy
... additional arguments affecting the summary produced (see base function summary).

Value

Information on the geographic bounds of the dataset (minimum and maximum latitude and longitude), resolution of the matrix in minutes, statistics on the depth data (e.g. min, max, median...), and a preview of the data.

class(atl)

# summarize data of class bathy
summary(atl)
```

trans.mat

Transition matrix

Description

Creates a transition object to be used by `lc.dist` to compute least cost distances between locations.

Usage

```
trans.mat(bathy, min.depth=0, max.depth=NULL)
```

Arguments

`bathy` A matrix of class `bathy`.

`min.depth`, `max.depth`

Numeric. The range of depth between which the path will be possible. The default (`min.depth=0` and `max.depth=NULL`) indicates that the transition between cells of the grid is possible between 0 meters depth and the maximum depth of `bathy`. See details

Details

trans.mat creates a transition object usable by lc.dist to compute least cost distances between a set of locations. trans.mat relies on the function raster from package raster (Hijmans & van Etten, 2012. <http://CRAN.R-project.org/package=raster>) and on transition from package gdistance (van Etten, 2011. <http://CRAN.R-project.org/package=gdistance>).

The transition object contains the probability of transition from one cell of a bathymetric grid to adjacent cells and depends on user defined parameters. trans.mat is especially useful when least cost distances need to be calculated between several locations at sea. The default values for min.depth and max.depth ensure that the path computed by lc.dist will be the shortest path possible at sea avoiding land masses. The path can be constrained to a given depth range by setting manually min.depth and max.depth. For instance, it is possible to limit the possible paths to the continental shelf by setting max.depth=-200. Inaccuracies of the bathymetric data can occasionally result in paths crossing land masses. Setting min.depth to low negative values (e.g. -10 meters) can limit this problem.

trans.mat takes also advantage of the function geoCorrection from package gdistance (van Etten, 2012. <http://CRAN.R-project.org/package=gdistance>) to take into account map distortions over large areas.

Value

A transition object.

Warning

Please be aware that the use of trans.mat can be time consuming for large bathymetric datasets. The function takes about one minute to compute a transition matrix for the hawaii bathymetric data (bathymetric data of class bathy with 599 rows and 419 columns, see [hawaii](#)) on a MacBook Pro with a 2.66 GHz Intel Core i7 processor and 4 Go of RAM.
