

Package ‘GPLTR’

July 2, 2014

Type Package

Title Generalized Partially Linear Tree-based Regression Model

Version 0.95

Date 2014-05-27

Author Cyprien Mbogning <cyprien.mbogning@inserm.fr> and Wilson Toussile

Maintainer Cyprien Mbogning <cyprien.mbogning@gmail.com>

Description Package for generalized partially linear tree-based regression model, combining a generalized linear model with an additional tree part on the same scale.

---------------	---

Description

Package for generalize partially linear tree-based regression model, combining a generalized linear model with an additional tree part on the same scale.

Details

Package: GPLTR
 Type: Package
 Version: 0.95
 Date: 2014-05-27
 License: GPL(>=2.0)

Author(s)

Cyprien Mbogning and Wilson Toussile
 Maintainer: Cyprien Mbogning <cyprien.mbogning@gmail.com>

Examples

```
##load the data set

#data(data_pltr)
#args.rpart <- list(minbucket = 40, maxdepth = 10, cp = 0)
```

```
#family <- "binomial"
#Y.name <- "Y"
#X.names <- "G1"
#G.names <- paste("G", 2:15, sep="")

# build a maximal tree

#fit_pltr <- pltr.glm(data_pltr, Y.name, X.names, G.names, args.rpart = args.rpart,
#                   family = family, iterMax = 4, iterMin = 3)

#plot(fit_pltr$tree, main = 'MAXIMAL TREE')
#text(fit_pltr$tree, minlength = 0L, xpd = TRUE)

## pruned back the maximal tree by BIC or AIC criterion

#tree_select <- best.tree.BIC.AIC(xtree = fit_pltr$tree, data_pltr, Y.name,
#                                X.names, G.names, family = family)

#plot(tree_select$tree$BIC, main = 'BIC TREE')
#text(tree_select$tree$BIC, minlength = 0L, xpd = TRUE)

## pruned back the maximal tree by a cross-validation procedure

#tree_selected <- best.tree.CV(fit_pltr$tree, data_pltr, Y.name, X.names, G.names,
#                              family = family, args.rpart = args.rpart, epsi = 0.001, iterMax = 15,
#                              iterMin = 8, ncv = 10)

#plot(tree_selected$tree, main = 'CV TREE')
#text(tree_selected$tree, minlength = 0L, xpd = TRUE)

## Compute the p-value of the selected tree by BIC

#args.parallel = list(numWorkers = 1, type = "PSOCK")
#index = tree_select$best_index[[1]]
#p_value <- p.val.tree(xtree = fit_pltr$tree, data_pltr, Y.name, X.names, G.names,
#                      B = 10, args.rpart = args.rpart, epsi = 1e-3,
#                      iterMax = 15, iterMin = 8, family = family, LB = FALSE,
#                      args.parallel = args.parallel, index = index)

## select an test the selected tree by a pametric bootstrap procedure

#best_bootstrap <- best.tree.bootstrap(fit_pltr$tree, data_pltr, Y.name, X.names,
#                                     G.names, B = 10, BB = 10, args.rpart = args.rpart, epsi = 0.001,
#                                     iterMax = 15, iterMin = 8, family = family, LEVEL = 0.05, LB = FALSE,
#                                     args.parallel = args.parallel)

## bagging a set of PLTR predictors

#bagging_pred <- bagging.pltr(data_pltr, Y.name, X.names, G.names, family,
#                            args.rpart, epsi = 0.001, iterMax = 15, iterMin = 8, LB = FALSE,
#                            args.parallel = args.parallel, Bag = 20, Pred_Data = data.frame())
```

```

#####
## Example on a public dataset: the burn data
#####
## The burn data are also displayed in the KMsurv package
#####
data(burn)

## Build the rpart tree with all the variables

cfit = rpart(D2 ~ Z1 + Z2 + Z3 + Z4 + Z5 + Z6 + Z7 + Z8 + Z9 + Z10 + Z11,
             data = burn, method = "class")

plot(cfit, main = 'rpart tree')
text(cfit, xpd = TRUE)

## fit the PLTR model after adjusting on gender (Z2) using the proposed method

args.rpart <- list(minbucket = 10, maxdepth = 4, cp = 0)
family <- "binomial"
X.names = "Z2"
Y.name = "D2"
G.names = c('Z1','Z3','Z4','Z5','Z6','Z7','Z8','Z9','Z10','Z11')
fit_pltr <- pltr.glm(burn, Y.name, X.names, G.names, args.rpart = args.rpart,
                    family = family, iterMax = 4, iterMin = 3, verbose = FALSE)

tree_select <- best.tree.BIC.AIC(xtree = fit_pltr$tree, burn ,Y.name,
                                X.names, G.names, family = family)

plot(tree_select$tree$BIC, main = 'new PLTR tree')
text(tree_select$tree$BIC, xpd = TRUE)
summary(tree_select$fit_glm$BIC)

## fit the PLTR model after adjusting on gender (Z2) using the original method

## uncomment the following code and set numWorkers = 1 on a windows platform

# args.parallel = list(numWorkers = 10, type = "PSOCK")
#best_bootstrap <- best.tree.bootstrap(fit_pltr$tree, burn, Y.name, X.names,
#                                     G.names, B = 2000, BB = 2000, args.rpart = args.rpart, epsi = 0.008,
#                                     iterMax = 6, iterMin = 5, family = family, LEVEL = 0.05, LB = FALSE,
#                                     args.parallel = args.parallel, verbose = FALSE)
# plot(best_bootstrap$selected_model$tree, main = 'original method')
# text(best_bootstrap$selected_model$tree, xpd = TRUE)

```

Description

bagging procedure to aggregate several PLTR models for accurate prediction

Usage

```
bagging.pltr(xdata, Y.name, X.names, G.names, family = "binomial",
args.rpart, epsi = 0.001, iterMax = 15, iterMin = 8, LB = FALSE,
args.parallel = list(numWorkers = 10, type = "PSOCK"),
Bag = 20, Pred_Data = data.frame(), verbose = TRUE, doprune = TRUE)
```

Arguments

xdata	the learning data frame
Y.name	the name of the binary dependent variable
X.names	the names of independent variables to consider in the linear part of the glm and as offset in the tree part
G.names	the names of independent variables to consider in the tree part of the hybrid glm.
family	the glm family considered depending on the type of the dependent variable (only the binomial family works in this function for the moment) .
args.rpart	a list of options that control details of the rpart algorithm. minbucket: the minimum number of observations in any terminal <leaf> node; cp: complexity parameter (Any split that does not decrease the overall lack of fit by a factor of cp is not attempted); maxdepth: the maximum depth of any node of the final tree, with the root node counted as depth 0. ... See rpart.control for further details
epsi	a treshold value to check the convergence of the algorithm
iterMax	the maximal number of iteration to consider
iterMin	the minimum number of iteration to consider
LB	a binary indicator with values TRUE or FALSE indicating weither the loading is balanced or not in the parallel computing. It is nevertheless useless on a windows platform. See parallel
args.parallel	a list of two elements containing the number of workers and the type of parallelization to achieve see parallel .
Bag	The number of Bagging samples to consider
Pred_Data	An optional data frame to validate the bagging procedure (the test dataset)
verbose	Logical; TRUE for printing progress during the computation (helpful for debugging)
doprune	a binary indicator with values TRUE or FALSE indicating weither the set of trees in the bagging procedure are pruned (by a BIC procedure) or not

Value

A list with ten elements

IND_OOB	A list of length Bag containing the Out Of Bag (OOB) individuals for each PLTR model.
E00B	The OOB error of the bagging procedure.
OOB_ERROR	The OOB error on the complete learning sample
OOB_ERRORS_PBP	A vector of length Bag containing OOB error of each PLTR model in the bagging sequence.
OOB_ERRORS_PBP	The mean of OOB_ERRORS_PBP.
Tree_BAG	A list of length Bag containing the bagging trees
Glm_BAG	A list of length Bag containing the bagging pltr model; could be helpful for prediction of new features.
TEST	A value of "000" if Pred_Data is not available. A list of three elements otherwise: PRED_ERROR: the estimated error of the Bagging procedure on the test sample; PRED_IND: a matrix with the prediction of the testing data individuals with each bagging PLTR model (column by column); FINAL_PRED_IND: A vector with the final prediction of each individual of the testing data by the bagging procedure (the modal prediction).
Timediff	The execution time of the bagging procedure

Examples

```
##load the data set
#data(data_pltr)
#args.rpart <- list(minbucket = 40, maxdepth = 10, cp = 0)
#family <- "binomial"
#Y.name <- "Y"
#X.names <- "G1"
#G.names <- paste("G", 2:15, sep="")

## bagging a set of PLTR predictors
#args.parallel = list(numWorkers = 1, type = "PSOCK")

#bagging_pred <- bagging.pltr(data_pltr, Y.name, X.names, G.names, family,
#                               args.rpart,epsi = 0.001, iterMax = 15, iterMin = 8, LB = FALSE,
#                               args.parallel = args.parallel, Bag = 20, Pred_Data = data.frame())
```

best.tree.BIC.AIC *Prunning the Maximal tree*

Description

this function is set to prune back the maximal tree by using the BIC or the AIC criterion.

Usage

```
best.tree.BIC.AIC(xtree, xdata, Y.name, X.names,  
                  G.names, family = "binomial", verbose = TRUE)
```

Arguments

xtree	a tree to prune
xdata	the dataset used to build the tree
Y.name	the name of the dependent variable
X.names	the names of independent variables to consider in the linear part of the glm
G.names	the names of independent variables to consider in the tree part of the hybrid glm.
family	the glm family considered depending on the type of the dependent variable.
verbose	Logical; TRUE for printing progress during the computation (helpful for debugging)

Value

a list of four elements:

best_index	The size of the selected trees by BIC and AIC
tree	The selected trees by BIC and AIC
fit_glm	The fitted pltr models selected with BIC, and AIC
Timediff	The execution time of the selection procedure

[best.tree.CV, pltr.glm](#)

Examples

```
##load the data set
#data(data_pltr)
#args.rpart <- list(minbucket = 40, maxdepth = 10, cp = 0)
#family <- "binomial"
#Y.name <- "Y"
#X.names <- "G1"
#G.names <- paste("G", 2:15, sep="")

## build a maximal tree

#fit_pltr <- pltr.glm(data_pltr, Y.name, X.names, G.names, args.rpart = args.rpart,
#                    family = family, iterMax = 15, iterMin = 8)

##pruned back the maximal tree by BIC or AIC criterion

#tree_select <- best.tree.BIC.AIC(xtree = fit_pltr$tree, data_pltr, Y.name,
#                                X.names, G.names, family = family)

#plot(tree_select$tree$BIC, main = 'BIC TREE')
#text(tree_select$tree$BIC, minlength = 0L, xpd = TRUE)
```

best.tree.bootstrap *parametric bootstrap on a pltr model*

Description

a parametric bootstrap procedure to select and test at the same time the selected tree

Usage

```
best.tree.bootstrap(xtree, xdata, Y.name, X.names, G.names, B = 10, BB = 10,
args.rpart = list(cp = 0, minbucket = 20, maxdepth = 10), epsi = 0.001,
iterMax = 15, iterMin = 8, family = "gaussian", LEVEL = 0.05, LB = FALSE,
args.parallel = list(numWorkers = 10, type = "PSOCK"), verbose = TRUE)
```

Arguments

xtree	the maximal tree obtained by the function <code>pltr.glm</code>
xdata	the data frame used to build xtree
Y.name	the name of the dependent variable
X.names	the names of independent variables to consider in the linear part of the glm
G.names	the names of independent variables to consider in the tree part of the hybrid glm.

B	the size of the bootstrap sample
BB	the size of the bootstrap sample to compute the adjusted p-value
args.rpart	a list of options that control details of the rpart algorithm. minbucket: the minimum number of observations in any terminal <leaf> node; cp: complexity parameter (Any split that does not decrease the overall lack of fit by a factor of cp is not attempted); maxdepth: the maximum depth of any node of the final tree, with the root node counted as depth 0. ... See rpart.control for further details
epsi	a treshold value to check the convergence of the algorithm
iterMax	the maximal number of iteration to consider
iterMin	the minimum number of iteration to consider
family	the glm family considered depending on the type of the dependent variable.
LEVEL	the level of the test
LB	a binary indicator with values TRUE or FALSE indicating weither the loading is balanced or not in the parallel computing. It is useless on a windows platform.
args.parallel	a list of two elements containing the number of workers and the type of parallelization to achieve
verbose	Logical; TRUE for printing progress during the computation (helpful for debugging)

Value

a list with six elements	
selected_model	a list with the fit of the selected pltr model <code>fit_glm</code> , the selected tree <code>tree</code> , the p-value of the selected tree <code>p.value</code> , the ajusted p-value of the selected tree <code>adj_p.value</code> and an indicator <code>Tree_Selected</code> to assess wether the test is significant or not.
fit_glm	the fitted pltr model under the null hypothesis if the test is not significant
Timediff	The execution time of the parametric bootstrap procedure
comp_p_values	The P-values of the competing trees
Badj	The number of samples used in the inner level of the procedure
BBadj	The number of samples used in the outer level of the procedure

```

best.tree.CV

Pruning the Maximal tree

Description

this function is set to prune back the maximal tree by using a K-fold cross-validation procedure.

Usage

```
best.tree.CV(xtree, xdata, Y.name, X.names, G.names, family = "binomial",
args.rpart = list(cp = 0, minbucket = 20, maxdepth = 10), epsi = 0.001,
iterMax = 15, iterMin = 8, ncv = 10, verbose = TRUE)
```

Arguments

xtree	a tree to prune
xdata	the dataset used to build the tree
Y.name	the name of the dependent variable
X.names	the names of independent variables to consider in the linear part of the glm
G.names	the names of independent variables to consider in the tree part of the hybrid glm.
family	the glm family considered depending on the type of the dependent variable.

args.rpart	a list of options that control details of the rpart algorithm. minbucket: the minimum number of observations in any terminal <leaf> node; cp: complexity parameter (Any split that does not decrease the overall lack of fit by a factor of cp is not attempted); maxdepth: the maximum depth of any node of the final tree, with the root node counted as depth 0. ... See rpart.control for further details
epsi	a threshold value to check the convergence of the algorithm
iterMax	the maximal number of iteration to consider
iterMin	the minimum number of iteration to consider
ncv	The number of folds to consider for the cross-validation
verbose	Logical; TRUE for printing progress during the computation (helpful for debugging)

Value

a list of five elements:

best_index	The size of the selected tree by the cross-validation procedure
tree	The selected tree by CV
fit_glm	The fitted glmtr models selected with CV
CV_ERRORS	A list of two elements containing the cross-validation error of the selected tree by the CV procedure and a vector of cross-validation errors of all the competing models
Timediff	The execution time of the CV procedure

```

best.tree.permute *permutation test on a pltr model*

Description

a unified permutation test procedure to select and test at the same time the selected tree

Usage

```

best.tree.permute(xtree, xdata, Y.name, X.names, G.names, B = 10,
  args.rpart = list(cp = 0, minbucket = 20, maxdepth = 10), epsi = 0.001,
  iterMax = 15, iterMin = 8, family = "binomial", LEVEL = 0.05,
  LB = FALSE, args.parallel = list(numWorkers = 10, type = "PSOCK"), verbose = TRUE)

```

Arguments

xtree	the maximal tree obtained by the function <code>pltr.glm</code>
xdata	the data frame used to build xtree
Y.name	the name of the dependent variable
X.names	the names of independent variables to consider in the linear part of the glm. For this function, only a binary variable is supported.
G.names	the names of independent variables to consider in the tree part of the hybrid glm.
B	the size of the bootstrap sample
args.rpart	a list of options that control details of the rpart algorithm. <code>minbucket</code> : the minimum number of observations in any terminal <leaf> node; <code>cp</code> : complexity parameter (Any split that does not decrease the overall lack of fit by a factor of <code>cp</code> is not attempted); <code>maxdepth</code> : the maximum depth of any node of the final tree, with the root node counted as depth 0. ... See rpart.control for further details
epsi	a threshold value to check the convergence of the algorithm
iterMax	the maximal number of iteration to consider

iterMin	the minimum number of iteration to consider
family	the binomial family.
LEVEL	the level of the test
LB	a binary indicator with values TRUE or FALSE indicating whether the loading is balanced or not in the parallel computing. It is useless on a windows platform.
args.parallel	a list of two elements containing the number of workers and the type of parallelization to achieve
verbose	Logical; TRUE for printing progress during the computation (helpful for debugging)

Value

a list with six elements:

p.val_selected	the adjusted p-value of the selected tree
selected_model	a list with the fit of the selected pltr model fit_glm, the selected tree tree and the p-value of the selected tree without adjusting for multiple comparisons p.value
fit_glm	the fitted pltr model under the null hypothesis if the test is not significant
Timediff	The execution time of the permutation test procedure
comp_p_values	The P-values of the competing trees
Badj	The number of samples used inside the procedure

burn

burn dataset

Description

The burn data frame has 154 rows and 17 columns.

Usage

```
data(burn)
```

Format

A data frame with 154 observations on the following 17 variables.

Obs Observation number

Z1 Treatment: 0=routine bathing 1=Body cleansing

Z2 Gender (0=male 1=female)

Z3 Race: 0=nonwhite 1=white

Z4 Percentage of total surface area burned

Z5 Burn site indicator: head 1=yes, 0=no

Z6 Burn site indicator: buttock 1=yes, 0=no

Z7 Burn site indicator: trunk 1=yes, 0=no

Z8 Burn site indicator: upper leg 1=yes, 0=no

Z9 Burn site indicator: lower leg 1=yes, 0=no

Z10 Burn site indicator: respiratory tract 1=yes, 0=no

Z11 Type of burn: 1=chemical, 2=scald, 3=electric, 4=flame

T1 Time to excision or on study time

D1 Excision indicator: 1=yes 0=no

T2 Time to prophylactic antibiotic treatment or on study time

D2 Prophylactic antibiotic treatment: 1=yes 0=no

T3 Time to straphylocous aureaus infection or on study time

D3 Straphylocous aureaus infection: 1=yes 0=no

## maybe str(burn) ;
```

data_pltr	<i>gpltr data example</i>
-----------	---------------------------

Description

A data frame to test the functions of the package

Usage

```
data(data_pltr)
```

Format

A data frame with 3000 observations on the following 16 variables.

G1 a numeric vector
G2 a factor with levels 0 1
G3 a factor with levels 0 1
G4 a factor with levels 0 1
G5 a factor with levels 0 1
G6 a binary numeric vector
G7 a binary numeric vector
G8 a binary numeric vector
G9 a binary numeric vector
G10 a binary numeric vector
G11 a binary numeric vector
G12 a binary numeric vector
G13 a binary numeric vector
G14 a binary numeric vector
G15 a binary numeric vector
Y a binary numeric vector

Details

The numeric variable G1 is considered as offset in the simulated PLTR model; the variables G2,...,G5 are used to simulate the tree part, while G6,...,G15 are noise variables.

Examples

```
data(data_pltr)
## maybe str(data_pltr) ...
```

nested.trees	<i>compute the nested trees</i>
--------------	---------------------------------

Description

Compute a set of nested competing trees for the pruning phase

Usage

```
nested.trees(xtree, xdata, Y.name, X.names, G.names, MaxTreeSize = NULL,
family = "gaussian", verbose = TRUE)
```

Arguments

xtree	a tree inheriting to the rpart method
xdata	the dataset used to build the tree
Y.name	the name of the dependent variable in the tree model
X.names	the names of independent variables considered as offset in the tree model
G.names	the names of independent variables used to build the tree.
MaxTreeSize	The maximal size of the competing trees
family	the glm family considered depending on the type of the dependent variable.
verbose	Logical; TRUE for printing progress during the computation (helpful for debugging)

Value

a list with 4 elements:

leaves	a list of leaves of the competing trees to consider for the optimal tree
null_deviance	the deviance of the null model (linear part of the glm)
deviances	a vector of deviances of the competing PLTR models
diff_deviances	a vector of the deviance differences between the competing PLTR models and the null model

Author(s)

Cyprien Mbogning

Examples

```
##load the data set

#data(data_pltr)
#args.rpart <- list(minbucket = 40, maxdepth = 10, cp = 0)
#family <- "binomial"
#Y.name <- "Y"
#X.names <- "G1"
#G.names <- paste("G", 2:15, sep="")

## build a maximal tree

#fit_pltr <- pltr.glm(data_pltr, Y.name, X.names, G.names, args.rpart = args.rpart,
#                   family = family, iterMax = 15, iterMin = 8)

## compute the competing trees
#nested_trees <- nested.trees(fit_pltr$tree, data_pltr, Y.name, X.names, G.names,
#                              MaxTreeSize = 10, family = family)
```

p.val.tree

*Compute the p-value***Description**

Test whether the selected tree by either BIC, AIC or CV procedure is significantly associated to the dependent variable or not, while adjusting for a confounding effect.

Usage

```
p.val.tree(xtree, xdata, Y.name, X.names, G.names, B = 10, args.rpart =
list(minbucket = 40, maxdepth = 10, cp = 0), epsi = 0.001, iterMax = 15,
iterMin = 8, family = "binomial", LB = FALSE,
args.parallel = list(numWorkers = 10, type = "PSOCK"), index = 4, verbose = TRUE)
```

Arguments

xtree	the maximal tree obtained by the function pltr.glm
xdata	the data frame used to build xtree
Y.name	the name of the dependent variable
X.names	the names of independent variables to consider in the linear part of the glm
G.names	the names of independent variables to consider in the tree part of the hybrid glm.
B	the resampling size of the deviance difference

<code>args.rpart</code>	a list of options that control details of the <code>rpart</code> algorithm. <code>minbucket</code> : the minimum number of observations in any terminal <leaf> node; <code>cp</code> : complexity parameter (Any split that does not decrease the overall lack of fit by a factor of <code>cp</code> is not attempted); <code>maxdepth</code> : the maximum depth of any node of the final tree, with the root node counted as depth 0. ... See rpart.control for further details
<code>epsi</code>	a threshold value to check the convergence of the algorithm
<code>iterMax</code>	the maximal number of iteration to consider
<code>iterMin</code>	the minimum number of iteration to consider
<code>family</code>	the glm family considered depending on the type of the dependent variable.
<code>LB</code>	a binary indicator with values <code>TRUE</code> or <code>FALSE</code> indicating whether the loadings are balanced or not in the parallel computing
<code>args.parallel</code>	a list of two elements containing the number of workers and the type of parallelization to achieve
<code>index</code>	the size of the selected tree (by the functions best.tree.BIC.AIC or best.tree.CV) using one of the proposed criteria
<code>verbose</code>	Logical; <code>TRUE</code> for printing progress during the computation (helpful for debugging)

Value

A list of three elements:

<code>p.value</code>	The P-value of the selected tree
<code>Timediff</code>	The execution time of the test procedure
<code>Badj</code>	The number of samples used inside the the procedure

```

pltr.glm

Partially tree-based regression model function

Description

The `pltr.glm` function is designed to fit an hybrid glm model with an additive tree part on a glm scale.

Usage

```

pltr.glm(data, Y.name, X.names, G.names, family = "binomial",
         args.rpart = list(cp = 0, minbucket = 20, maxdepth = 10),
         epsi = 0.001, iterMax = 15, iterMin = 8, verbose = TRUE)

```

Arguments

<code>data</code>	a data frame containing the variables in the model
<code>Y.name</code>	the name of the dependent variable
<code>X.names</code>	the names of independent variables to consider in the linear part of the glm

G.names	the names of independent variables to consider in the tree part of the hybrid glm.
family	the glm family considered depending on the type of the dependent variable.
args.rpart	a list of options that control details of the rpart algorithm. minbucket: the minimum number of observations in any terminal <leaf> node; cp: complexity parameter (Any split that does not decrease the overall lack of fit by a factor of cp is not attempted); maxdepth: the maximum depth of any node of the final tree, with the root node counted as depth 0. ... See rpart.control for further details
epsi	a threshold value to check the convergence of the algorithm
iterMax	the maximal number of iteration to consider
iterMin	the minimum number of iteration to consider
verbose	Logical; TRUE for printing progress during the computation (helpful for debugging)

Details

The `pltr.glm` function use an iterative procedure to fit the linear part of the glm and the tree part. The tree obtained at the convergence of the procedure is a maximal tree which overfits the data. It's then mandatory to pruned back this tree by using one of the proposed criteria (BIC, AIC and CV).

Value

A list with four elements:

fit	the global glm fitted at the end of the algorithm
tree	the maximal tree obtained at the end of the algorithm
nber_iter	the number of iterations used by the algorithm
Timediff	The execution time of the iterative procedure

Note

The tree obtained at the end of these iterative procedure usually overfits the data. It's therefore mandatory to use either `best.tree.BIC.AIC` or `best.tree.CV` to pruned back the tree.

##load the data set

data(data_pltr)
args.rpart <- list(minbucket = 40, maxdepth = 10, cp = 0)
family <- "binomial"
Y.name <- "Y"
X.names <- "G1"
G.names <- paste("G", 2:15, sep="")

## build a maximal tree (uncomment the following code)

#fit_pltr <- pltr.glm(data_pltr, Y.name, X.names, G.names, args.rpart = args.rpart,
#                    family = family, iterMax = 15, iterMin = 8)

#plot(fit_pltr$tree, main = 'MAXIMAL TREE')
#text(fit_pltr$tree, minlength = 0L, xpd = TRUE)
```

predict_bagg.pltr *prediction on new features*

Description

Predict new features using a set of bagging pltr models

Usage

```
predict_bagg.pltr(bag_pltr, Y.name, newdata, type = "response",
                 threshold = 0.5)
```

Arguments

bag_pltr	a list containing the set of bagging pltr model obtained with the function bagging.pltr
Y.name	the name of the binary dependent variable
newdata	a data frame in which to look for variables with which to predict.
type	the type of prediction required. type = "response" is the default; It gives the predicted probabilities. At this stage of the package, only this type is take into account. Other types like "link" and "terms" aren't supported yet.
threshold	the cutoff value for binary prediction

Value

A list with 8 elements

FINAL_PRED_IND1

A vector with the final prediction of each individual of the testing data by the bagging procedure (the modal prediction).

FINAL_PRED_IND2

A vector with the final prediction of each individual of the testing data by the bagging procedure using the mean estimated probability.

PRED_IND_MAT

A matrix containing the predicted values of the test sample (predictor by predictor in the bagging sequence.) column by column.

PRED_ERROR1

the estimated error of the Bagging procedure on the test sample using FINAL_PRED_IND1.

PRED_ERROR2

the estimated error of the Bagging procedure on the test sample using FINAL_PRED_IND2.

PROB_MAT

A matrix of estimated probabilities on testing sample individuals by each predictor of the bagging sequence.

CONF1

The confusion matrix using FINAL_PRED_IND1

CONF2

The confusion matrix using FINAL_PRED_IND2

tree2glm

tree to GLM

Description

fit the PLTR model for a given tree. The tree is transform in indicators covariates.

Usage

```
tree2glm(xtree, xdata, Y.name, X.names, G.names, family = "gaussian")
```

Arguments

xtree	a tree inherits from the rpart method
xdata	a data frame containing the variables in the model
Y.name	the name of the dependent variable
X.names	the names of independent variables to consider in the linear part of the glm
G.names	the names of independent variables considered in the tree part.
family	the glm family considered depending on the type of the dependent variable.

Value

the fitted model (fit)

Author(s)

Cyprien Mbogning

Examples

```
##load the data set

#data(data_pltr)
#args.rpart <- list(minbucket = 40, cp = 0)
#family <- "binomial"
#Y.name <- "Y"
#X.names <- "G1"
#G.names <- paste("G", 2:15, sep="")

## build a maximal tree

#fit_pltr <- pltr.glm(data_pltr, Y.name, X.names, G.names, args.rpart = args.rpart,
#                   family = family, iterMax = 15, iterMin = 8)

#fit_glm <- tree2glm(fit_pltr$tree, data_pltr, Y.name, X.names, G.names,
#                   family = family)

#summary(fit_glm)
```

tree2indicators *From a tree to indicators*

Description

Coerces a given tree structure to binary covariates.

Usage

```
tree2indicators(fit)
```

Arguments

`fit` a tree structure inheriting to the `rpart` method

Value

a list of indicators

Author(s)

Cyprien Mbogning

Examples

```
##load the data set

#data(data_pltr)
#args.rpart <- list(minbucket = 40, xval = 10, cp = 0)
#family <- "binomial"
#Y.name <- "Y"
#X.names <- "G1"
#G.names <- paste("G", 2:15, sep="")

## build a maximal tree

#fit_pltr <- pltr.glm(data_pltr, Y.name, X.names, G.names, args.rpart = args.rpart,
#                   family = family, iterMax = 15, iterMin = 8)

##Compute a list of indicator from the leaves of the tree fitted tree

#tree2indicators(fit_pltr$tree)
```
