

Package ‘CBPS’

September 21, 2015

Version 0.10

Date 2015-09-07

Title Covariate Balancing Propensity Score

Author

Christian Fong <christianfong@stanford.edu>, Marc Ratkovic <ratkovic@princeton.edu>, Chad Hazlett <chazlett@ucla.edu>, Kosuke Imai <kimai@princeton.edu>

Maintainer Christian Fong <christianfong@stanford.edu>

Depends R (>= 2.14), MASS, MatchIt, nnet, numDeriv

Imports

Description Implements the covariate balancing propensity score (CBPS) proposed by Imai and Ratkovic (2014; JRSSB). The propensity score is estimated such that it maximizes the resulting covariate balance as well as the prediction of treatment assignment. The method, therefore, avoids an iteration between model fitting and balance checking. The package also implements several extensions of the CBPS beyond the cross-sectional, binary treatment setting. The current version implements the CBPS for longitudinal settings so that it can be used in conjunction with marginal structural models (Imai and Ratkovic, 2014), treatments with three- and four-valued treatment variables, continuous-valued treatments (Fong, Hazlett, and Imai, 2015), and the situation with multiple distinct binary treatments administered simultaneously. In the future it will be extended to other settings including the generalization of experimental and instrumental variable estimates.

balance	<i>Optimal Covariate Balance</i>
---------	----------------------------------

Description

Returns the mean and standardized mean associated with each treatment group, before and after weighting.

Usage

```
## S3 method for class 'CBPS'
balance(object, ...)
```

Arguments

object	A CBPS, npCBPS, or CBMSM object.
...	Additional arguments to be passed to balance.

Details

For binary and multi-valued treatments as well as marginal structural models, each of the matrices' rows are the covariates and whose columns are the weighted mean, and standardized mean associated with each treatment group. The standardized mean is the weighted mean divided by the standard deviation of the covariate for the whole population. For continuous treatments, returns the absolute Pearson correlation between the treatment and each covariate.

Value

Returns a list of two matrices, "original" (before weighting) and "balanced" (after weighting).

Author(s)

Christian Fong, Marc Ratkovic, and Kosuke Imai.

Examples

```

Blackwell

Blackwell Data for Covariate Balancing Propensity Score

Description

This data set gives the outcomes as well as treatment assignments and covariates for the example from Blackwell (2013).

Usage

```
Blackwell
```

Format

A data frame consisting of 13 columns (including treatment assignment, time, and identifier vectors) and 570 observations.

Source

d.gone.neg is the treatment. d.gone.neg.l1, d.gone.neg.l2, and d.gone.neg.l3 are lagged treatment variables. camp.length, deminc, base.poll, base.und, and office covariates. year is the year of the particular race, and time goes from the first measurement (time = 1) to the election (time = 5). demName is the identifier, and demprcnt is the outcome.

CBMSM	<i>Covariate Balancing Propensity Score (CBPS) for Marginal Structural Models</i>
-------	---

Description

CBMSM estimates propensity scores such that both covariate balance and prediction of treatment assignment are maximized. With longitudinal data, the method returns marginal structural model weights that can be entered directly into a linear model. The method also handles multiple binary treatments administered concurrently.

Usage

```
CBMSM(formula, id, time, data, type="MSM", twostep = TRUE,
msm.variance = "approx", time.vary = FALSE, ...)
CBMSM.fit(treat, X, id, time, MultiBin.fit, twostep,
msm.variance, time.vary, ...)
```

Arguments

formula	A list of formulas of the form $treat \sim X$. The function assumes that there is one formula for each time, and they are ordered from the first time to the last time.
id	A vector which identifies the unit associated with each row of treat and X.
time	A vector which identifies the time period associated with each row of treat and X.
data	An optional data frame, list or environment (or object coercible by <code>as.data.frame</code> to a data frame) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which CBMSM is called.
twostep	Set to TRUE to use a two-step estimator, which will run substantially faster than continuous-updating. Default is FALSE, which uses the continuous-updating estimator described by Imai and Ratkovic (2014).
msm.variance	Default is FALSE, which uses the low-rank approximation of the variance described in Imai and Ratkovic (2014). Set to TRUE to use the full variance matrix.

<code>time.vary</code>	Default is FALSE, which uses the same coefficients across time period. Set to TRUE to fit one set per time period.
<code>treat</code>	A vector of treatment assignments. For N observations over T time periods, the length of treat should be N*T.
<code>X</code>	A covariate matrix. For N observations over T time periods, X should have N*T rows.
<code>type</code>	"MSM" for a marginal structural model, with multiple time periods or "MultiBin" for multiple binary treatments at the same time period.
<code>MultiBin.fit</code>	A parameter for whether the multiple binary treatments occur concurrently (FALSE) or over consecutive time periods (TRUE) as in a marginal structural model. Setting <code>type = "MultiBin"</code> when calling <code>CBMSM</code> will set <code>MultiBin.fit</code> to TRUE when <code>CBMSM.fit</code> is called.
<code>...</code>	Other parameters to be passed through to <code>optim()</code>

Details

Fits covariate balancing propensity scores for marginal structural models.

Value

<code>weights</code>	The optimal weights.
<code>fitted.values</code>	The fitted propensity score for each observation.
<code>y</code>	The treatment vector used.
<code>x</code>	The covariate matrix.
<code>id</code>	The vector id used in <code>CBMSM.fit</code> .
<code>time</code>	The vector time used in <code>CBMSM.fit</code> .
<code>model</code>	The model frame.
<code>call</code>	The matched call.
<code>formula</code>	The formula supplied.
<code>data</code>	The data argument.
<code>treat.hist</code>	A matrix of the treatment history, with each observation in rows and time in columns.
<code>treat.cum</code>	A vector of the cumulative treatment history, by individual.

Author(s)

Marc Ratkovic, Christian Fong, and Kosuke Imai; The `CBMSM` function is based on the code for version 2.15.0 of the `glm` function implemented in the `stats` package, originally written by Simon Davies. This documentation is likewise modeled on the documentation for `glm` and borrows its language where the arguments and values are the same.

CBPS

Covariate Balancing Propensity Score (CBPS) Estimation

Description

CBPS estimates propensity scores such that both covariate balance and prediction of treatment assignment are maximized. The method, therefore, avoids an iterative process between model fitting and balance checking and implements both simultaneously. For cross-sectional data, the method can take continuous treatments and treatments with a control (baseline) condition and either 1, 2, or 3 distinct treatment conditions.

Usage

```

CBPS(formula, data, na.action, ATT = 1, iterations = 1000,
      standardize = TRUE, method = "over", twostep = TRUE, ...)
CBPS.fit(treat, X, ATT, method, iterations,
         standardize, twostep, ...)

```

Arguments

formula	An object of class formula (or one that can be coerced to that class): a symbolic description of the model to be fitted.
---------	--

<code>data</code>	An optional data frame, list or environment (or object coercible by <code>as.data.frame</code> to a data frame) containing the variables in the model. If not found in <code>data</code> , the variables are taken from <code>environment(formula)</code> , typically the environment from which CBPS is called.
<code>na.action</code>	A function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of options, and is <code>na.fail</code> if that is unset.
<code>ATT</code>	Default is 1, which finds the average treatment effect on the treated interpreting the second level of the treatment factor as the treatment. Set to 2 to find the ATT interpreting the first level of the treatment factor as the treatment. Set to 0 to find the average treatment effect. For non-binary treatments, only the ATE is available.
<code>iterations</code>	An optional parameter for the maximum number of iterations for the optimization. Default is 1000.
<code>standardize</code>	Default is TRUE, which normalizes weights to sum to 1 within each treatment group. For continuous treatments, normalizes weights to sum up to 1 for the entire sample. Set to FALSE to return Horvitz-Thompson weights.
<code>method</code>	Choose "over" to fit an over-identified model that combines the propensity score and covariate balancing conditions; choose "exact" to fit a model that only contains the covariate balancing conditions.
<code>twostep</code>	Default is TRUE for a two-step estimator, which will run substantially faster than continuous-updating. Set to FALSE to use the continuous-updating estimator described by Imai and Ratkovic (2014).
<code>treat</code>	A vector of treatment assignments. Binary or multi-valued treatments should be factors. Continuous treatments should be numeric.
<code>X</code>	A covariate matrix.
<code>...</code>	Other parameters to be passed through to <code>optim()</code>

Details

Fits covariate balancing propensity scores.

Value

<code>fitted.values</code>	The fitted propensity score
<code>deviance</code>	Minus twice the log-likelihood of the CBPS fit
<code>weights</code>	The optimal weights. Let $\pi_i = f(T_i X_i)$. For binary ATE, these are given by $\frac{T_i}{\pi_i} + \frac{(1-T_i)}{(1-\pi_i)}$. For binary ATT, these are given by $\frac{n}{n_t} * T_i + \frac{n}{n_t} * \frac{1-T_i}{1-\pi_i}$. For multi_valued treatments, these are given by $\sum_{j=0}^{J-1} T_{i,j} / \pi_{i,j}$. For continuous treatments, these are given by $\frac{f(T_i)}{f(T_i X_i)}$. These expressions for weights are all before standardization (i.e. with <code>standardize=FALSE</code>). Standardization will make weights sum to 1 within each treatment group. For continuous treatment, standardization will make all weights sum to 1.
<code>y</code>	The treatment vector used
<code>x</code>	The covariate matrix

model	The model frame
converged	Convergence value. Returned from the call to <code>optim()</code> .
call	The matched call
formula	The formula supplied
data	The data argument
coefficients	A named vector of coefficients
sigmasq	The sigma-squared value, for continuous treatments only
J	The J-statistic at convergence
mle.J	The J-statistic for the parameters from maximum likelihood estimation
var	The covariance matrix, evaluated numerically from <code>optim()</code> .

```

Description

This data set gives the outcomes as well as treatment assignments and covariates for the econometric evaluation of training programs in LaLonde (1986).

Usage

LaLonde

Format

A data frame consisting of 5 columns (including a treatment assignment vector) and 2787 observations.

Source

Data from the National Supported Work Study. A benchmark matching dataset. Columns consist of an indicator for whether the observed unit was in the experimental subset; an indicator for whether the individual received the treatment; age in years; schooling in years; indicators for black and Hispanic; an indicator for marriage status, one of married; an indicator for no high school degree; and reported earnings in 1974, 1975, and 1978. 1974 and 1975 earnings are pre-treatment. 1978 earnings is taken as the outcome variable.

npCBPS

Non-Parametric Covariate Balancing Propensity Score (npCBPS) Estimation

Description

npCBPS is a method to estimate weights interpretable as (stabilized) inverse generalized propensity score weights, $w_i = f(T_i)/f(T_i|X)$, without actually estimating a model for the treatment to arrive at $f(T|X)$ estimates. In brief, this works by maximizing the empirical likelihood of observing the values of treatment and covariates that were observed, while constraining the weights to be those that (a) ensure balance on the covariates, and (b) maintain the original means of the treatment and covariates. In the continuous treatment context, this balance on covariates means zero correlation of each covariate with the treatment. Furthermore, we apply a Bayesian variant that allows the correlation of each covariate with the treatment to be slightly non-zero, as might be expected in a given finite sample.

Usage

```
npCBPS(formula, data, na.action, corprior = 0.1, print.level = 0, ...)
npCBPS.fit(treat, X, corprior, print.level, ...)
```

Arguments

formula	An object of class formula (or one that can be coerced to that class): a symbolic description of the model to be fitted.
data	An optional data frame, list or environment (or object coercible by <code>as.data.frame</code> to a data frame) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which CBPS is called.
na.action	A function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of options, and is <code>na.fail</code> if that is unset.
corprior	Prior hyperparameter controlling the expected amount of correlation between each covariate and the treatment. Specifically, the amount of correlation between the k -dimensional covariates, X , and the treatment T after weighting is assumed to have prior distribution $MVN(0, \sigma^2 I_k)$. We conceptualize σ^2 as a tuning parameter to be used pragmatically. It's default of 0.1 ensures that the balance constraints are not too harsh, and that a solution is likely to exist. Once the algorithm works at such a high value of σ^2 , the user may wish to attempt values closer to 0 to get finer balance.
print.level	Controls verbosity of output to the screen while npCBPS runs. At the default of <code>print.level=0</code> , little output is produced. If <code>print.level>0</code> , it outputs diagnostics including the log posterior (<code>log_post</code>), the log empirical likelihood associated with the weights (<code>log_el</code>), and the log prior probability of the (weighted) correlation of treatment with the covariates.
treat	A vector of treatment assignments. Binary or multi-valued treatments should be factors. Continuous treatments should be numeric.
X	A covariate matrix.
...	Other parameters to be passed.

Details

Estimates non-parametric covariate balancing propensity score weights.

Value

weights	The optimal weights
y	The treatment vector used
x	The covariate matrix
model	The model frame
call	The matched call
formula	The formula supplied
data	The data argument
log.p.eta	The log density for the (weighted) correlation of the covariates with the treatment, given the choice of prior (<code>corprior</code>)
log.el	The log empirical likelihood of the observed data at the chosen set of IPW weights.

eta	A vector describing the correlation between the treatment and each covariate on the weighted data at the solution.
sumw0	The sum of weights, provided as a check on convergence. This is always 1 when convergence occurs unproblematically. If it differs from 1 substantially, no solution perfectly satisfying the conditions was found, and the user may consider a larger value of corprior.

plot.CBMSM	<i>Plotting Covariate Balancing Propensity Score Estimation for Marginal Structural Models</i>
------------	--

Description

Plots the absolute difference in standardized means before and after weighting.

Usage

```
## S3 method for class 'CBMSM'
plot(x, covars = NULL, silent = TRUE, boxplot = FALSE, ...)
```

Arguments

x	an object of class “CBMSM”.
covars	Indices of the covariates to be plotted (excluding the intercept). For example, if only the first two covariates from balance are desired, set covars to 1:2. The default is NULL, which plots all covariates.
silent	If set to FALSE, returns the absolute imbalance for each treatment history pair before and after weighting. This helps the user to create his or her own customized plot. Default is TRUE, which returns nothing.
boxplot	If set to TRUE, returns a boxplot summarizing the imbalance on the covariates instead of a point for each covariate. Useful if there are many covariates.
...	Additional arguments to be passed to plot.

Details

Covariate balance is improved if the plot’s points are below the plotted line of $y=x$.

Value

The x-axis gives the imbalance for each covariate-treatment history pair without any weighting, and the y-axis gives the imbalance for each covariate-treatment history pair after CBMSM weighting. Imbalance is measured as the absolute difference in standardized means for the two treatment histories. Means are standardized by the standard deviation of the covariate in the full sample.

plot.CBPS

Plotting Covariate Balancing Propensity Score Estimation

Description

Plots the absolute difference in standardized means before and after weighting.

Usage

```
## S3 method for class 'CBPS'
plot(x, covars = NULL, silent = TRUE, boxplot = FALSE, ...)
```

Arguments

x	an object of class “CBPS” or “npCBPS”, usually, a result of a call to CBPS or npCBPS.
covars	Indices of the covariates to be plotted (excluding the intercept). For example, if only the first two covariates from balance are desired, set covars to 1:2. The default is NULL, which plots all covariates.
silent	If set to FALSE, returns the imbalances used to construct the plot. Default is TRUE, which returns nothing.
boxplot	If set to TRUE, returns a boxplot summarizing the imbalance on the covariates instead of a point for each covariate. Useful if there are many covariates.
...	Additional arguments to be passed to plot.

Details

The "Before Weighting" plot gives the balance before weighting, and the "After Weighting" plot gives the balance after weighting.

Value

For binary and multi-valued treatments, plots the absolute difference in standardized means by contrast for all covariates before and after weighting. This quantity for a single covariate and a given pair of treatment conditions is given by $\frac{\sum_{i=1}^n w_i * (T_i == 1) * X_i}{\sum_{i=1}^n (T_i == 1) * w_i} - \frac{\sum_{i=1}^n w_i * (T_i == 0) * X_i}{\sum_{i=1}^n (T_i == 0) * w_i}$. For continuous treatments, plots the weighted absolute Pearson correlation between the treatment and each covariate. See https://en.wikipedia.org/wiki/Pearson_product-moment_correlation_coefficient#Weighted_correlation_coefficient.

summary.CBPS

Summarizing Covariate Balancing Propensity Score Estimation

Description

Prints a summary of a fitted CBPS object.

Usage

```
## S3 method for class 'CBPS'
summary(object, ...)
```

Arguments

object an object of class “CBPS”, usually, a result of a call to CBPS.
 ... Additional arguments to be passed to summary.

Details

Prints a summary of a CBPS object, in a format similar to glm. The variance matrix is calculated from the numerical Hessian at convergence of CBPS.

Value

call The matched call.
 deviance.residuals The five number summary and the mean of the deviance residuals.
 coefficients A table including the estimate for the each coefficient and the standard error, z-value, and two-sided p-value for these estimates.
 J Hansen’s J-Statistic for the fitted model.
 Log-Likelihood The log-likelihood of the fitted model.

Author(s)

vcov.CBPS

Calculate Variance-Covariance Matrix for a Fitted CBPS Object

Description

vcov.CBPS Returns the variance-covariance matrix of the main parameters of a fitted CBPS object.

Usage

```
## S3 method for class 'CBPS'
vcov(object, ...)
```

Arguments

object An object of class formula (or one that can be coerced to that class): a symbolic description of the model to be fitted.
 ... Additional arguments to be passed to vcov.CBPS

Details

This is the CBPS implementation of the generic function `vcov()`.

Value

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model.

Author(s)

Christian Fong, Marc Ratkovic, and Kosuke Imai.

References

This documentation is modeled on the documentation of the generic `vcov`.

Examples

```
## Not run:
###
### Example: Variance-Covariance Matrix
###

##Load the LaLonde data
data(LaLonde)
## Estimate CBPS via logistic regression
fit <- CBPS(treat ~ age + educ + re75 + re74 + I(re75==0) + I(re74==0),
  data = LaLonde, ATT = TRUE)
## Get the variance-covariance matrix.
vcov(fit)

## End(Not run)
```
