Package 'fitdistrplus'

November 30, 2015

Title Help to Fit of a Parametric Distribution to Non-Censored or Censored Data

Version 1.0-6

Date 2015-11-20

Description Extends the fitdistr function (of the MASS package) with several functions to help the fit of a parametric distribution to non-censored or censored data. Censored data may contain left censored, right censored and interval censored values, with several lower and upper bounds. In addition to maximum likelihood estimation (MLE), the package provides moment matching (MME), quantile matching (QME) and maximum goodness-of-fit estimation (MGE) methods (available only for non-censored data). Weighted versions of MLE, MME and QME are available.

Depends R (>= 3.2.0), MASS, grDevices

Imports stats, survival

Suggests actuar, rgenoud, mc2d, gamlss.dist

R topics documented:

`bootdist` *Bootstrap simulation of uncertainty for non-censored data*

Description

Uses parametric or nonparametric bootstrap resampling in order to simulate uncertainty in the parameters of the distribution fitted to non-censored data.

Usage

```
bootdist(f, bootmethod="param", niter=1001, silent=TRUE)
## S3 method for class 'bootdist'
print(x, ...)
## S3 method for class 'bootdist'
plot(x, main="Bootstrapped values of parameters", enhance=FALSE,
    trueval=NULL, rampcol=NULL, nbgrid = 100, nbcol = 100, ...)
## S3 method for class 'bootdist'
summary(object, ...)
```

Arguments

f	An object of class "fitdist", output of the fitdist function.
bootmethod	A character string coding for the type of resampling : "param" for a parametric resampling and "nonparam" for a nonparametric resampling of data.
niter	The number of samples drawn by bootstrap.
silent	A logical to remove or show warnings and errors when bootstraping.
x	An object of class "bootdist".
object	An object of class "bootdist".
main	an overall title for the plot: see title, default to "Bootstrapped values of parameters".
enhance	a logical to get an enhanced plot.
trueval	when relevant, a numeric vector with the true value of parameters (for backfitting purposes).
rampcol	colors to interpolate; must be a valid argument to colorRampPalette().
nbgrid	Number of grid points in each direction. Can be scalar or a length-2 integer vector.
nbcol	an integer argument, the required number of colors
...	Further arguments to be passed to generic methods

Details

Samples are drawn by parametric bootstrap (resampling from the distribution fitted by fitdist) or nonparametric bootstrap (resampling with replacement from the data set). On each bootstrap sample the function mledist (or mmedist, qmedist, mgedist according to the component f$method of the object of class "fitdist") is used to estimate bootstrapped values of parameters. When that function fails to converge, NA values are returned. Medians and 2.5 and 97.5 percentiles are computed by removing NA values. The medians and the 95 percent confidence intervals of parameters (2.5 and 97.5 percentiles) are printed in the summary. If inferior to the whole number of iterations, the number of iterations for which the function converges is also printed in the summary.

By default (when enhance=FALSE), the plot of an object of class "bootdist" consists in a scatterplot or a matrix of scatterplots of the bootstrapped values of parameters. It uses the function stripchart when the fitted distribution is characterized by only one parameter, the function plot when there are two paramters and the function pairs in other cases. In these last cases, it provides a representation of the joint uncertainty distribution of the fitted parameters.

When enhance=TRUE, a personalized plot version of pairs is used where upper graphs are scatterplots and lower graphs are heatmap image using image based on a kernel based estimator for the 2D density function (using kde2d from MASS package). Arguments rampcol, nbgrid, nbcol can be used to customize the plots. Defautls values are rampcol=c("green", "yellow", "orange", "red"), nbcol=100 (see colorRampPalette()), nbgrid=100 (see kde2d). In addition, when fitting parameters on simulated datasets for backtesting purposes, an additional argument trueval can be used to plot a cross at the true value.

Value

`bootdist` returns an object of class `"bootdist"`, a list with 6 components,

`estim`	a data frame containing the bootstrapped values of parameters.
`converg`	a vector containing the codes for convergence obtained if an iterative method is used to estimate parameters on each bootstraped data set (and 0 if a closed formula is used).
`method`	A character string coding for the type of resampling : `"param"` for a parametric resampling and `"nonparam"` for a nonparametric resampling.
`nbboot`	The number of samples drawn by bootstrap.
`CI`	bootstrap medians and 95 percent confidence percentile intervals of parameters.
`fitpart`	The object of class `"fitdist"` on which the bootstrap procedure was applied.

Generic functions:

`print` The print of a `"bootdist"` object shows the bootstrap parameter estimates. If inferior to the whole number of bootstrap iterations, the number of iterations for which the estimation converges is also printed.

`summary` The summary provides the median and 2.5 and 97.5 percentiles of each parameter. If inferior to the whole number of bootstrap iterations, the number of iterations for which the estimation converges is also printed in the summary.

`plot` The plot shows the bootstrap estimates with `stripchart` function for univariate parameters and `plot` function for multivariate parameters.

```

`bootdistcens` *Bootstrap simulation of uncertainty for censored data*

Description

Uses nonparametric bootstrap resampling in order to simulate uncertainty in the parameters of the distribution fitted to censored data.

Usage

```
bootdistcens(f, niter = 1001, silent=TRUE)
## S3 method for class 'bootdistcens'
print(x, ...)
```

```
## S3 method for class 'bootdistcens'
plot(x, ...)
## S3 method for class 'bootdistcens'
summary(object, ...)
```

Arguments

f	An object of class "fitdistcens", output of the fitdistcens function.
niter	The number of samples drawn by bootstrap.
silent	A logical to remove or show warnings and errors when bootstraping.
x	An object of class "bootdistcens".
object	An object of class "bootdistcens".
...	Further arguments to be passed to generic methods.

Details

Samples are drawn by nonparametric bootstrap (resampling with replacement from the data set). On each bootstrap sample the function mledist is used to estimate bootstrapped values of parameters. When mledist fails to converge, NA values are returned. Medians and 2.5 and 97.5 percentiles are computed by removing NA values. The medians and the 95 percent confidence intervals of parameters (2.5 and 97.5 percentiles) are printed in the summary. If inferior to the whole number of iterations, the number of iterations for which mledist converges is also printed in the summary.

The plot of an object of class "bootdistcens" consists in a scatterplot or a matrix of scatterplots of the bootstrapped values of parameters. It uses the function stripchart when the fitted distribution is characterized by only one parameter, and the function plot in other cases. In these last cases, it provides a representation of the joint uncertainty distribution of the fitted parameters.

Value

bootdistcens returns an object of class "bootdistcens", a list with 6 components,

estim	a data frame containing the bootstrapped values of parameters.
converg	a vector containing the codes for convergence of the iterative method used to estimate parameters on each bootstraped data set.
method	A character string coding for the type of resampling : in this case "nonparam" as it is the only available method for censored data.
nbboot	The number of samples drawn by bootstrap.
CI	bootstrap medians and 95 percent confidence percentile intervals of parameters.
fitpart	The object of class "fitdistcens" on which the bootstrap procedure was applied.

Generic functions:

print The print of a "bootdistcens" object shows the bootstrap parameter estimates. If inferior to the whole number of bootstrap iterations, the number of iterations for which the estimation converges is also printed.

`summary` The summary provides the median and 2.5 and 97.5 percentiles of each parameter. If inferior to the whole number of bootstrap iterations, the number of iterations for which the estimation converges is also printed in the summary.

`plot` The plot shows the bootstrap estimates with the `stripchart` function for univariate parameters and `plot` function for multivariate parameters.

`cdfcompcens` *Compares various fitted distributions to censored data on a cdf plot*

Description

Plots the empirical cumulative distribution (censored continuous data) with theoretical ones corresponding to various fitted distributions.

Usage

```
cdfcompcens(ft, xlim, ylim, xlogscale = FALSE, ylogscale = FALSE, main, xlab, ylab,
   datacol, fitlty, fitcol, addlegend = TRUE, legendtext, xlegend = "bottomright",
    ylegend = NULL, lines01 = FALSE, Turnbull.confint = FALSE, ...)
```

Arguments

`ft`	One `"fitdistcens"` object or a list of objects of class `"fitdistcens"`.
`xlim`	The x-limits of the plot.
`ylim`	The y-limits of the plot.
`xlogscale`	If `TRUE`, uses a logarithmic scale for the x-axis.
`ylogscale`	If `TRUE`, uses a logarithmic scale for the y-axis.
`main`	A main title for the plot, see also `title`.
`xlab`	A label for the x-axis, defaults to a description of `x`.
`ylab`	A label for the y-axis, defaults to a description of `y`.
`datacol`	A specification of the color to be used in plotting data points.
`fitcol`	A (vector of) color(s) to plot fitted distributions. If there are fewer colors than fits they are recycled in the standard fashion.
`fitlty`	A (vector of) line type(s) to plot fitted distributions. If there are fewer colors than fits they are recycled in the standard fashion. See also `par`.
`addlegend`	If `TRUE`, a legend is added to the plot.
`legendtext`	A character or expression vector of length ≥ 1 to appear in the legend, see also `legend`.
`xlegend, ylegend`	The x and y co-ordinates to be used to position the legend. They can be specified by keyword or in any way which is accepted by 'xy.coords': see `legend` for details.
`lines01`	A logical to plot two horizontal lines at `h=0` and `h=1`.
`Turnbull.confint`	if TRUE, confidence intervals will be added to the Turnbull plot of the empirical distribution.
`...`	Further graphical arguments passed to graphical functions used in `cdfcompcens`.

Details

Empirical and theoretical distributions are plotted in cdf. The EM approach of Turnbull (Turnbull, 1974) is used to compute the overall empirical cdf curve, with confidence intervals if `Turnbull.confint` is `TRUE`, by calls to functions `survfit` and `plot.survfit` from the `survival` package. By default a legend is added to the plot. Many graphical arguments are optional, dedicated to personalize the plot, and fixed to default values if omitted.

danish *Danish reinsurance claim dataset*

Description

The univariate dataset was collected at Copenhagen Reinsurance and comprise 2167 fire losses over the period 1980 to 1990. They have been adjusted for inflation to reflect 1985 values and are expressed in millions of Danish Krone.

The multivariate data set is the same data as above but the total claim has been divided into a building loss, a loss of contents and a loss of profits.

Usage

```
data(danishuni)
data(danishmulti)
```

Format

`danishuni` contains two columns:

`Date` The day of claim occurence.

`Loss` The total loss amount in millions of Danish Krone (DKK).

`danishmulti` contains five columns:

`Date` The day of claim occurence.

`Building` The loss amount (mDKK) of the building coverage.

`Contents` The loss amount (mDKK) of the contents coverage.

`Profits` The loss amount (mDKK) of the profit coverage.

`Total` The total loss amount (mDKK).

All columns are numeric except Date columns of class Date.

    "grey50", "grey75"))
```

`descdist` *Description of an empirical distribution for non-censored data*

Description

Computes descriptive parameters of an empirical distribution for non-censored data and provides a skewness-kurtosis plot.

Usage

```
descdist(data, discrete = FALSE, boot = NULL, method = "unbiased",
graph = TRUE, obs.col = "darkblue", obs.pch = 16, boot.col = "orange")

## S3 method for class 'descdist'
print(x, ...)
```

Arguments

`data`	A numeric vector.
`discrete`	If `TRUE`, the distribution is considered as discrete.

boot	If not NULL, boot values of skewness and kurtosis are plotted from bootstrap samples of data. boot must be fixed in this case to an integer above 10.
method	"unbiased" for unbiased estimated values of statistics or "sample" for sample values.
graph	If FALSE, the skewness-kurtosis graph is not plotted.
obs.col	Color used for the observed point on the skewness-kurtosis graph.
obs.pch	plotting character used for the observed point on the skewness-kurtosis graph.
boot.col	Color used for bootstrap sample of points on the skewness-kurtosis graph.
x	An object of class "descdist".
...	Further arguments to be passed to generic functions

Details

Minimum, maximum, median, mean, sample sd, and sample (if method=="sample") or by default unbiased estimations of skewness and Pearsons's kurtosis values are printed (Sokal and Rohlf, 1995). A skewness-kurtosis plot such as the one proposed by Cullen and Frey (1999) is given for the empirical distribution. On this plot, values for common distributions are also displayed as a tools to help the choice of distributions to fit to data. For some distributions (normal, uniform, logistic, exponential for example), there is only one possible value for the skewness and the kurtosis (for a normal distribution for example, skewness = 0 and kurtosis = 3), and the distribution is thus represented by a point on the plot. For other distributions, areas of possible values are represented, consisting in lines (gamma and lognormal distributions for example), or larger areas (beta distribution for example). The Weibull distribution is not represented on the graph but it is indicated on the legend that shapes close to lognormal and gamma distributions may be obtained with this distribution.

In order to take into account the uncertainty of the estimated values of kurtosis and skewness from data, the data set may be bootstraped by fixing the argument boot to an integer above 10. boot values of skewness and kurtosis corresponding to the boot bootstrap samples are then computed and reported in blue color on the skewness-kurtosis plot.

If discrete is TRUE, the represented distributions are the Poisson, negative binomial distributions, and the normal distribution to which previous discrete distributions may converge. If discrete is FALSE, these are uniform, normal, logistic, lognormal, beta and gamma distributions.

Value

descdist returns a list with 7 components,

min	the minimum value
max	the maximum value
median	the median value
mean	the mean value
sd	the standard deviation sample or estimated value
skewness	the skewness sample or estimated value
kurtosis	the kurtosis sample or estimated value
method	the method specified in input ("unbiased" for unbiased estimated values of statistics or "sample" for sample values.

`fitdist` *Fit of univariate distributions to non-censored data*

Description

Fit of univariate distributions to non-censored data by maximum likelihood (mle), moment matching (mme), quantile matching (qme) or maximizing goodness-of-fit estimation (mge). The latter is also known as minimizing distance estimation. Generic methods are `print`, `plot`, `summary`, `quantile`, `logLik`, `vcov` and `coef`.

Usage

```
fitdist(data, distr, method = c("mle", "mme", "qme", "mge"),
    start=NULL, fix.arg=NULL, discrete, keepdata = TRUE, keepdata.nb=100, ...)

## S3 method for class 'fitdist'
print(x, ...)

## S3 method for class 'fitdist'
plot(x, breaks="default", ...)

## S3 method for class 'fitdist'
summary(object, ...)

## S3 method for class 'fitdist'
logLik(object, ...)

## S3 method for class 'fitdist'
vcov(object, ...)

## S3 method for class 'fitdist'
coef(object, ...)
```

Arguments

`data`	A numeric vector.
`distr`	A character string `"name"` naming a distribution for which the corresponding density function `dname`, the corresponding distribution function `pname` and the corresponding quantile function `qname` must be defined, or directly the density function.
`method`	A character string coding for the fitting method: `"mle"` for 'maximum likelihood estimation', `"mme"` for 'moment matching estimation', `"qme"` for 'quantile matching estimation' and `"mge"` for 'maximum goodness-of-fit estimation'.
`start`	A named list giving the initial values of parameters of the named distribution or a function of data computing initial values and returning a named list. This argument may be omitted (default) for some distributions for which reasonable starting values are computed (see the 'details' section of `mledist`). It may not be into account for closed-form formulas.

fix.arg	An optional named list giving the values of fixed parameters of the named distribution or a function of data computing (fixed) parameter values and returning a named list. Parameters with fixed value are thus NOT estimated by this maximum likelihood procedure. The use of this argument is not possible if method="mme" and a closed-form formula is used.
x	An object of class "fitdist".
object	An object of class "fitdist".
breaks	If "default" the histogram is plotted with the function hist with its default breaks definition. Else breaks is passed to the function hist. This argument is not taken into account with discrete distributions: "binom", "nbinom", "geom", "hyper" and "pois".
keepdata	a logical. If TRUE, dataset is returned, otherwise only a sample subset is returned.
keepdata.nb	When keepdata=FALSE, the length (>1) of the subset returned.
discrete	If TRUE, the distribution is considered as discrete. If discrete is missing, discrete is automaticaly set to TRUE when distr belongs to "binom", "nbinom", "geom", "hyper" or "pois" and to FALSE in the other cases. It is thus recommended to enter this argument when using another discrete distribution. This argument will not directly affect the results of the fit but will be passed to functions gofstat, plotdist and cdfcomp.
...	Further arguments to be passed to generic functions, or to one of the functions "mledist", "mmedist", "qmedist" or "mgedist" depending of the chosen method. See mledist, mmedist, qmedist, mgedist for details on parameter estimation.

Details

It is assumed that the distr argument specifies the distribution by the probability density function, the cumulative distribution function and the quantile function (d, p, q).

The four possible fitting methods are described below:

When method="mle" Maximum likelihood estimation consists in maximizing the log-likelihood. A numerical optimization is carried out in mledist via optim to find the best values (see mledist for details).

When method="mme" Moment matching estimation consists in equalizing theoretical and empirical moments. Estimated values of the distribution parameters are computed by a closed-form formula for the following distributions : "norm", "lnorm", "pois", "exp", "gamma", "nbinom", "geom", "beta", "unif" and "logis". Otherwise the theoretical and the empirical moments are matched numerically, by minimization of the sum of squared differences between observed and theoretical moments. In this last case, further arguments are needed in the call to fitdist: order and memp (see mmedist for details).

When method = "qme" Quantile matching estimation consists in equalizing theoretical and empirical quantile. A numerical optimization is carried out in qmedist via optim to minimize of the sum of squared differences between observed and theoretical quantiles. The use of this method requires an additional argument probs, defined as the numeric vector of the probabilities for which the quantile(s) is(are) to be matched (see qmedist for details).

When `method = "mge"` Maximum goodness-of-fit estimation consists in maximizing a goodness-of-fit statistics. A numerical optimization is carried out in `mgedist` via `optim` to minimize the goodness-of-fit distance. The use of this method requires an additional argument `gof` coding for the goodness-of-fit distance chosen. One can use the classical Cramer-von Mises distance (`"CvM"`), the classical Kolmogorov-Smirnov distance (`"KS"`), the classical Anderson-Darling distance (`"AD"`) which gives more weight to the tails of the distribution, or one of the variants of this last distance proposed by Luceno (2006) (see `mgedist` for more details). This method is not suitable for discrete distributions.

By default, direct optimization of the log-likelihood (or other criteria depending of the chosen method) is performed using `optim`, with the "Nelder-Mead" method for distributions characterized by more than one parameter and the "BFGS" method for distributions characterized by only one parameter. The optimization algorithm used in `optim` can be chosen or another optimization function can be specified using ... argument (see `mledist` for details). `start` may be omitted (i.e. `NULL`) for some classic distributions (see the 'details' section of `mledist`). Note that when errors are raised by `optim`, it's a good idea to start by adding traces during the optimization process by adding `control=list(trace=1, REPORT=1)` in ... argument.

Once the parameter(s) is(are) estimated, `fitdist` computes the log-likelihood for every estimation method and for maximum likelihood estimation the standard errors of the estimates calculated from the Hessian at the solution found by `optim` or by the user-supplied function passed to mledist.

By default (`keepdata = TRUE`), the returned object contains the data vector itself. For large dataset purposes, we can remove the original dataset from the output by setting `keepdata = FALSE`. In such a case, only `keepdata.nb` points (at most) are kept by random subsampling `keepdata.nb`-2 points from the dataset and adding the minimum and the maximum.

Weighted version of the estimation process is available for `method = "mle", "mme", "qme"` by using `weights=...`. See the corresponding man page for details. Weighted maximum GOF estimation (when `method = "mge"`) is not allowed. It is not yet possible to take into account weighths in functions `plotdist`, `plot.fitdist`, `cdfcomp`, `denscomp`, `ppcomp`, `qqcomp`, `gofstat` and `descdist` (developments planned in the future).

NB: if your data values are particularly small or large, a scaling may be needed before the optimization process. See example (14) in this man page and examples (14,15) in the test file of the package. Please also take a look at the `Rmpfr` package available on CRAN for numerical accuracy issues.

Value

`fitdist` returns an object of class `"fitdist"`, a list with the following components:

`estimate`	the parameter estimates.
`method`	the character string coding for the fitting method : `"mle"` for 'maximum likelihood estimation', `"mme"` for 'matching moment estimation', `"qme"` for 'matching quantile estimation' and `"mge"` for 'maximum goodness-of-fit estimation'.
`sd`	the estimated standard errors, `NA` if numerically not computable or `NULL` if not available.
`cor`	the estimated correlation matrix, `NA` if numerically not computable or `NULL` if not available.
`vcov`	the estimated variance-covariance matrix, `NULL` if not available.
`loglik`	the log-likelihood.

aic	the Akaike information criterion.
bic	the the so-called BIC or SBC (Schwarz Bayesian criterion).
n	the length of the data set.
data	the data set.
distname	the name of the distribution.
fix.arg	the named list giving the values of parameters of the named distribution that must be kept fixed rather than estimated by maximum likelihood or NULL if there are no such parameters.
fix.arg.fun	the function used to set the value of fix.arg or NULL.
discrete	the input argument or the automatic definition by the function to be passed to functions gofstat, plotdist and cdfcomp.
dots	the list of further arguments passed in ... to be used in bootdist in iterative calls to mledist, mmedist, qmedist, mgedist or NULL if no such arguments.
weights	the vector of weigths used in the estimation process or NULL.

Generic functions:

print The print of a "fitdist" object shows few traces about the fitting method and the fitted distribution.

summary The summary provides the parameter estimates of the fitted distribution, the log-likelihood, AIC and BIC statistics and when the maximum likelihood is used, the standard errors of the parameter estimates and the correlation matrix between parameter estimates.

plot The plot of an object of class "fitdist" returned by fitdist uses the function plotdist. An object of class "fitdist" or a list of objects of class "fitdist" corresponding to various fits using the same data set may also be plotted using a cdf plot (function cdfcomp), a density plot(function denscomp), a density Q-Q plot (function qqcomp), or a P-P plot (function ppcomp).

logLik Extracts the estimated log-likelihood from the "fitdist" object.

vcov Extracts the estimated var-covariance matrix from the "fitdist" object (only available When method = "mle").

coef Extracts the fitted coefficients from the "fitdist" object.

`fitdistcens` *Fitting of univariate distributions to censored data*

Description

Fits a univariate distribution to censored data by maximum likelihood.

Usage

```
fitdistcens(censdata, distr, start=NULL, fix.arg=NULL,
  keepdata = TRUE, keepdata.nb=100, ...)

## S3 method for class 'fitdistcens'
print(x, ...)

## S3 method for class 'fitdistcens'
plot(x, ...)

## S3 method for class 'fitdistcens'
summary(object, ...)

## S3 method for class 'fitdistcens'
logLik(object, ...)

## S3 method for class 'fitdistcens'
vcov(object, ...)

## S3 method for class 'fitdistcens'
coef(object, ...)
```

Arguments

`censdata`	A dataframe of two columns respectively named `left` and `right`, describing each observed value as an interval. The `left` column contains either `NA` for left censored observations, the left bound of the interval for interval censored observations, or the observed value for non-censored observations. The `right` column contains either `NA` for right censored observations, the right bound of the interval for interval censored observations, or the observed value for non-censored observations.
`distr`	A character string `"name"` naming a distribution, for which the corresponding density function `dname` and the corresponding distribution function `pname` must be defined, or directly the density function.
`start`	A named list giving the initial values of parameters of the named distribution. This argument may be omitted for some distributions for which reasonable starting values are computed (see the 'details' section of `mledist`).

fix.arg	An optional named list giving the values of parameters of the named distribution that must be kept fixed rather than estimated by maximum likelihood.
x	an object of class "fitdistcens".
object	an object of class "fitdistcens".
keepdata	a logical. If TRUE, dataset is returned, otherwise only a sample subset is returned.
keepdata.nb	When keepdata=FALSE, the length of the subset returned.
...	further arguments to be passed to generic functions, to the function plotdistcens in order to control the type of ecdf-plot used for censored data, or to the function mledist in order to control the optimization method.

Details

Maximum likelihood estimations of the distribution parameters are computed using the function mledist. By default direct optimization of the log-likelihood is performed using optim, with the "Nelder-Mead" method for distributions characterized by more than one parameter and the "BFGS" method for distributions characterized by only one parameter. The algorithm used in optim can be chosen or another optimization function can be specified using ... argument (see mledist for details). start may be omitted (i.e. NULL) for some classic distributions (see the 'details' section of mledist). Note that when errors are raised by optim, it's a good idea to start by adding traces during the optimization process by adding control=list(trace=1, REPORT=1) in ... argument.

The function is not able to fit a uniform distribution. With the parameter estimates, the function returns the log-likelihood and the standard errors of the estimates calculated from the Hessian at the solution found by optim or by the user-supplied function passed to mledist.

Weighted version of the estimation process is available for method = "mle" by using weights=.... See the corresponding man page for details. It is not yet possible to take into account weighths in functions plotdistcens, plot.fitdistcens and cdfcompcens (developments planned in the future).

Value

fitdistcens returns an object of class "fitdistcens", a list with the following components:

estimate	the parameter estimates.
sd	the estimated standard errors.
cor	the estimated correlation matrix, NA if numerically not computable or NULL if not available.
vcov	the estimated variance-covariance matrix, NULL if not available.
loglik	the log-likelihood.
aic	the Akaike information criterion.
bic	the the so-called BIC or SBC (Schwarz Bayesian criterion).
censdata	the censored data set.
distname	the name of the distribution.
fix.arg	the named list giving the values of parameters of the named distribution that must be kept fixed rather than estimated by maximum likelihood or NULL if there are no such parameters.

dots — the list of further arguments passed in ... to be used in bootdistcens to control the optimization method used in iterative calls to mledist or NULL if no such arguments.

weights — the vector of weigths used in the estimation process or NULL.

By default (keepdata = TRUE), the returned object contains the data vector itself. For large dataset purposes, we can remove the original dataset from the output by setting keepdata = FALSE. In such a case, only keepdata.nb points (at most) are kept by random subsampling keepdata.nb-4 points from the dataset and adding the component-wise minimum and maximum.

Generic functions:

print The print of a "fitdist" object shows few traces about the fitting method and the fitted distribution.

summary The summary provides the parameter estimates of the fitted distribution, the log-likelihood, AIC and BIC statistics, the standard errors of the parameter estimates and the correlation matrix between parameter estimates.

plot The plot of an object of class "fitdistcens" returned by fitdistcens uses the function plotdistcens.

logLik Extracts the estimated log-likelihood from the "fitdistcens" object.

vcov Extracts the estimated var-covariance matrix from the "fitdistcens" object (only available When method = "mle").

coef Extracts the fitted coefficients from the "fitdistcens" object.

`fluazinam` *Species-Sensitivity Distribution (SSD) for Fluazinam*

Description

48-hour acute toxicity values (EC50 values) for exposure of macroinvertebrates and zooplancton to fluazinam.

Usage

```
data(fluazinam)
```

Format

`fluazinam` is a data frame with 2 columns named left and right, describing each observed EC50 value (in micrograms per liter) as an interval. The left column contains either NA for left censored observations, the left bound of the interval for interval censored observations, or the observed value for non-censored observations. The right column contains either NA for right censored observations, the right bound of the interval for interval censored observations, or the observed value for noncensored observations.

`gofstat` *Goodness-of-fit statistics*

Description

Computes goodness-of-fit statistics for parametric distributions fitted to a same non-censored data set.

Usage

```
gofstat(f, chisqbreaks, meancount, discrete, fitnames=NULL)

## S3 method for class 'gofstat.fitdist'
print(x, ...)
```

Arguments

`f`	An object of class `"fitdist"`, output of the function `fitdist`, or a list of `"fitdist"` objects.
`chisqbreaks`	A numeric vector defining the breaks of the cells used to compute the chi-squared statistic. If omitted, these breaks are automatically computed from the data in order to reach roughly the same number of observations per cell, roughly equal to the argument `meancount`, or sligthly more if there are some ties.

meancount	The mean number of observations per cell expected for the definition of the breaks of the cells used to compute the chi-squared statistic. This argument will not be taken into account if the breaks are directly defined in the argument chisqbreaks. If chisqbreaks and meancount are both omitted, meancount is fixed in order to obtain roughly $(4n)^{2/5}$ cells with n the length of the dataset.
discrete	If TRUE, only the Chi-squared statistic and information criteria are computed. If missing, discrete is passed from the first object of class "fitdist" of the list f.
fitnames	A vector defining the names of the fits.
x	An object of class "fitdist".
...	Further arguments to be passed to generic functions.

Details

Goodness-of-fit statistics are computed. The Chi-squared statistic is computed using cells defined by the argument chisqbreaks or cells automatically defined from data, in order to reach roughly the same number of observations per cell, roughly equal to the argument meancount, or sligthly more if there are some ties. The choice to define cells from the empirical distribution (data), and not from the theoretical distribution, was done to enable the comparison of Chi-squared values obtained with different distributions fitted on a same data set. If chisqbreaks and meancount are both omitted, meancount is fixed in order to obtain roughly $(4n)^{2/5}$ cells, with n the length of the data set (Vose, 2000). The Chi-squared statistic is not computed if the program fails to define enough cells due to a too small dataset. When the Chi-squared statistic is computed, and if the degree of freedom (nb of cells - nb of parameters - 1) of the corresponding distribution is strictly positive, the p-value of the Chi-squared test is returned.

For continuous distributions, Kolmogorov-Smirnov, Cramer-von Mises and Anderson-Darling and statistics are also computed, as defined by Stephens (1986).

An approximate Kolmogorov-Smirnov test is performed by assuming the distribution parameters known. The critical value defined by Stephens (1986) for a completely specified distribution is used to reject or not the distribution at the significance level 0.05. Because of this approximation, the result of the test (decision of rejection of the distribution or not) is returned only for data sets with more than 30 observations. Note that this approximate test may be too conservative.

For data sets with more than 5 observations and for distributions for which the test is described by Stephens (1986) for maximum likelihood estimations ("exp", "cauchy", "gamma" and "weibull"), the Cramer-von Mises and Anderson-darling tests are performed as described by Stephens (1986). Those tests take into account the fact that the parameters are not known but estimated from the data by maximum likelihood. The result is the decision to reject or not the distribution at the significance level 0.05. Those tests are available only for maximum likelihood estimations.

Only recommended statistics are automatically printed, i.e. Cramer-von Mises, Anderson-Darling and Kolmogorov statistics for continuous distributions and Chi-squared statistics for discrete ones ("binom", "nbinom", "geom", "hyper" and "pois").

Results of the tests are not printed but stored in the output of the function.

Value

gof.stat returns an object of class "gofstat.fitdist" with following components,

chisq	a named vector with the Chi-squared statistics or NULL if not computed
chisqbreaks	common breaks used to define cells in the Chi-squared statistic
chisqpvalue	a named vector with the p-values of the Chi-squared statistic or NULL if not computed
chisqdf	a named vector with the degrees of freedom of the Chi-squared distribution or NULL if not computed
chisqtable	a table with observed and theoretical counts used for the Chi-squared calculations
cvm	a named vector of the Cramer-von Mises statistics or "not computed" if not computed
cvmtest	a named vector of the decisions of the Cramer-von Mises test or "not computed" if not computed
ad	a named vector with the Anderson-Darling statistics or "not computed" if not computed
adtest	a named vector with the decisions of the Anderson-Darling test or "not computed" if not computed
ks	a named vector with the Kolmogorov-Smirnov statistic or "not computed" if not computed
kstest	a named vector with the decisions of the Kolmogorov-Smirnov test or "not computed" if not computed
aic	a named vector with the values of the Aikake's Information Criterion.
bic	a named vector with the values of the Bayesian Information Criterion.
discrete	the input argument or the automatic definition by the function from the first object of class "fitdist" of the list in input.
nbfit	Number of fits in argument.

graphcomp *Graphical comparison of multiple fitted distributions (for non-censored data)*

Description

cdfcomp plots the empirical cumulative distribution against fitted distribution functions, denscomp plots the histogram against fitted density functions, qqcomp plots theoretical quantiles against empirical ones, ppcomp plots theoretical probabilities against empirical ones. Only cdfcomp is able to plot fits of a discrete distribution.

Usage

```
cdfcomp(ft, xlim, ylim, xlogscale = FALSE, ylogscale = FALSE, main, xlab, ylab,
    datapch, datacol, fitlty, fitcol, addlegend = TRUE, legendtext,
    xlegend = "bottomright", ylegend = NULL,
    horizontals = TRUE, verticals = FALSE, do.points = TRUE,
    use.ppoints = TRUE, a.ppoints = 0.5, lines01 = FALSE, discrete, ...)

denscomp(ft, xlim, ylim, probability = TRUE, main, xlab, ylab, datapch,
    datacol, fitlty, fitcol, addlegend = TRUE, legendtext, xlegend = "topright",
    ylegend = NULL, demp = FALSE, dempcol = "grey", ...)

qqcomp(ft, xlim, ylim, xlogscale = FALSE, ylogscale = FALSE, main, xlab, ylab,
    fitpch, fitcol, addlegend = TRUE, legendtext, xlegend = "bottomright",
    ylegend = NULL, use.ppoints = TRUE, a.ppoints = 0.5, line01 = TRUE,
    line01col = "black", line01lty = 1, ynoise = TRUE, ...)

ppcomp(ft, xlim, ylim, xlogscale = FALSE, ylogscale = FALSE, main, xlab, ylab,
    fitpch, fitcol, addlegend = TRUE, legendtext, xlegend = "bottomright",
    ylegend = NULL, use.ppoints = TRUE, a.ppoints = 0.5, line01 = TRUE,
    line01col = "black", line01lty = 1, ynoise = TRUE, ...)
```

Arguments

ft	One "fitdist" object or a list of objects of class "fitdist".
xlim	The x-limits of the plot.
ylim	The y-limits of the plot.
xlogscale	If TRUE, uses a logarithmic scale for the x-axis.
ylogscale	If TRUE, uses a logarithmic scale for the y-axis.
main	A main title for the plot, see also title.
xlab	A label for the x-axis, defaults to a description of x.
ylab	A label for the y-axis, defaults to a description of y.
datapch	An integer specifying a symbol to be used in plotting data points, see also points.

`datacol` A specification of the color to be used in plotting data points.

`fitcol` A (vector of) color(s) to plot fitted distributions. If there are fewer colors than fits they are recycled in the standard fashion.

`fitlty` A (vector of) line type(s) to plot fitted distributions/densities. If there are fewer colors than fits they are recycled in the standard fashion. See also `par`.

`fitpch` A (vector of) line type(s) to plot fitted quantiles/probabilities. If there are fewer colors than fits they are recycled in the standard fashion.

`addlegend` If `TRUE`, a legend is added to the plot.

`legendtext` A character or expression vector of length ≥ 1 to appear in the legend, see also `legend`.

`xlegend, ylegend`
The x and y co-ordinates to be used to position the legend. They can be specified by keyword or in any way which is accepted by 'xy.coords': see `legend` for details.

`horizontals` If `TRUE`, draws horizontal lines for the step empirical cdf function. See also `plot.stepfun`.

`do.points` logical; if `TRUE`, also draw points at the x-locations. Default is true. For large dataset (n > 1e4), `do.points` is ignored and no point is drawn.

`verticals` If `TRUE`, draws also vertical lines for the empirical cdf function. Only taken into account if `horizontals=TRUE`.

`use.ppoints` If `TRUE`, probability points of the empirical distribution are defined using function `ppoints` as `(1:n - a.ppoints)/(n - 2a.ppoints + 1)`. If `FALSE`, probability points are simply defined as `1:n / n`. This argument is ignored for discrete data.

`a.ppoints` If `use.ppoints=TRUE`, this is passed to function `ppoints`.

`lines01` A logical to plot two horizontal lines at `h=0` and `h=1` for `cdfcomp`.

`line01` A logical to plot an horizontal line $y = x$ for `qqcomp` and `ppcomp`.

`line01col, line01lty`
Color and line type for `line01`.

`demp` A logical to add the empirical density on the plot using the `density` function.

`dempcol` A color for the empirical density in case it is added on the plot.

`ynoise` A logical to add a small Gaussian noise when plotting empirical quantiles/probabilities for `qqcomp` and `ppcomp`.

`probability` A logical to use the probability scale for `denscomp`, see also `hist`.

`...` Further graphical arguments passed to graphical functions used in cdfcomp, denscomp, ppcomp and qqcomp.

`discrete` If `TRUE`, the distributions are considered discrete. If missing, `discrete` is passed from the first object of class `"fitdist"` of the list `ft`.

Details

cdfcomp provides a plot of the empirical distribution and each fitted distribution in cdf, by default using the Hazen's rule for the empirical distribution, with probability points defined as (1:n - 0.5)/n. If discrete is TRUE probability points are always defined as (1:n)/n. For large dataset (n > 1e4), no point is drawn but the line for ecdf is drawn instead. Note that when horizontals = FALSE, verticals = FALSE, do.p no empirical point is drawn, only the fitted cdf is shown.

denscomp provides a density plot of each fitted distribution with the histogram of the data (data are assumed continuous).

ppcomp provides a plot of the probabilities of each fitted distribution (x-axis) against the empirical probabilities (y-axis) by default defined as (1:n - 0.5)/n (data are assumed continuous). For large dataset (n > 1e4), lines are drawn instead of points.

qqcomp provides a plot of the quantiles of each theoretical distribution (x-axis) against the empirical quantiles of the data (y-axis), by default defining probability points as (1:n - 0.5)/n for theoretical quantile calculation (data are assumed continuous). For large dataset (n > 1e4), lines are drawn instead of points.

By default a legend is added to these plots. Many graphical arguments are optional, dedicated to personalize the plots, and fixed to default values if omitted.

groundbeef *Ground beef serving size data set*

Description

Serving sizes collected in a French survey, for ground beef patties consumed by children under 5 years old.

Usage

```
data(groundbeef)
```

Format

groundbeef is a data frame with 1 column (serving: serving sizes in grams)

Source

Delignette-Muller, M.L., Cornu, M. 2008. Quantitative risk assessment for *Escherichia coli* O157:H7 in frozen ground beef patties consumed by young children in French households. *International Journal of Food Microbiology*, **128**, 158-164.

Examples

```
# (1) load of data
#
data(groundbeef)

# (2) description and plot of data
#
serving <- groundbeef$serving
descdist(serving)
plotdist(serving)

plot(fitW)
gofstat(fitW)
```

mgedist *Maximum goodness-of-fit fit of univariate continuous distributions*

Description

Fit of univariate continuous distribution by maximizing goodness-of-fit (or minimizing distance) for non censored data.

Usage

```
mgedist(data, distr, gof = "CvM", start = NULL, fix.arg = NULL, optim.method = "default",
  lower = -Inf, upper = Inf, custom.optim = NULL, silent = TRUE, ...)
```

Arguments

data	A numeric vector for non censored data.
distr	A character string "name" naming a distribution for which the corresponding quantile function qname and the corresponding density distribution dname must be classically defined.
gof	A character string coding for the name of the goodness-of-fit distance used : "CvM" for Cramer-von Mises distance,"KS" for Kolmogorov-Smirnov distance, "AD" for Anderson-Darling distance, "ADR", "ADL", "AD2R", "AD2L" and "AD2" for variants of Anderson-Darling distance described by Luceno (2006).
start	A named list giving the initial values of parameters of the named distribution or a function of data computing initial values and returning a named list. This argument may be omitted (default) for some distributions for which reasonable starting values are computed (see the 'details' section of mledist).
fix.arg	An optional named list giving the values of fixed parameters of the named distribution or a function of data computing (fixed) parameter values and returning a named list. Parameters with fixed value are thus NOT estimated.
optim.method	"default" or optimization method to pass to optim.
lower	Left bounds on the parameters for the "L-BFGS-B" method (see optim).
upper	Right bounds on the parameters for the "L-BFGS-B" method (see optim).
custom.optim	a function carrying the optimization.
silent	A logical to remove or show warnings when bootstraping.
...	further arguments passed to the optim or custom.optim function.

Details

The mgedist function numerically maximizes goodness-of-fit, or minimizes a goodness-of-fit distance coded by the argument gof. One may use one of the classical distances defined in Stephens (1986), the Cramer-von Mises distance ("CvM"), the Kolmogorov-Smirnov distance ("KS") or the Anderson-Darling distance ("AD") which gives more weight to the tails of the distribution, or one of

the variants of this last distance proposed by Luceno (2006). The right-tail AD ("ADR") gives more weight only to the right tail, the left-tail AD ("ADL") gives more weight only to the left tail. Either of the tails, or both of them, can receive even larger weights by using second order Anderson-Darling Statistics (using "AD2R", "AD2L" or "AD2"). The optimization process is the same as mledist, see the 'details' section of mledist.

This function is not intended to be called directly but is internally called in fitdist and bootdist.

This function is intended to be used only with continuous distributions and weighted maximum goodness-of-fit estimation is not allowed.

NB: if your data values are particularly small or large, a scaling may be needed before the optimization process. See example (4).

Value

mgedist returns a list with following components,

estimate	the parameter estimates.
convergence	an integer code for the convergence of optim defined as below or defined by the user in the user-supplied optimization function. 0 indicates successful convergence. 1 indicates that the iteration limit of optim has been reached. 10 indicates degeneracy of the Nealder-Mead simplex. 100 indicates that optim encountered an internal error.
value	the value of the statistic distance corresponding to estimate.
hessian	a symmetric matrix computed by optim as an estimate of the Hessian at the solution found or computed in the user-supplied optimization function.
gof	the code of the goodness-of-fit distance maximized.
optim.function	the name of the optimization function used.
loglik	the log-likelihood value.
fix.arg	the named list giving the values of parameters of the named distribution that must kept fixed rather than estimated by maximum likelihood or NULL if there are no such parameters.
optim.method	when optim is used, the name of the algorithm used, NULL otherwise.
fix.arg.fun	the function used to set the value of fix.arg or NULL.

mledist *Maximum likelihood fit of univariate distributions*

Description

Fit of univariate distributions using maximum likelihood for censored or non censored data.

Usage

```
mledist(data, distr, start = NULL, fix.arg = NULL, optim.method = "default",
   lower = -Inf, upper = Inf, custom.optim = NULL, weights = NULL, silent = TRUE, ...)
```

Arguments

data	A numeric vector for non censored data or a dataframe of two columns respectively named `left` and `right`, describing each observed value as an interval for censored data. In that case the `left` column contains either `NA` for left censored observations, the left bound of the interval for interval censored observations, or the observed value for non-censored observations. The `right` column contains either `NA` for right censored observations, the right bound of the interval for interval censored observations, or the observed value for non-censored observations.
distr	A character string `"name"` naming a distribution for which the corresponding density function `dname` and the corresponding distribution function `pname` must be classically defined.
start	A named list giving the initial values of parameters of the named distribution or a function of data computing initial values and returning a named list. This argument may be omitted (default) for some distributions for which reasonable starting values are computed (see details).
fix.arg	An optional named list giving the values of fixed parameters of the named distribution or a function of data computing (fixed) parameter values and returning a named list. Parameters with fixed value are thus NOT estimated by this maximum likelihood procedure.
optim.method	`"default"` (see details) or an optimization method to pass to `optim`.
lower	Left bounds on the parameters for the `"L-BFGS-B"` method (see `optim`).
upper	Right bounds on the parameters for the `"L-BFGS-B"` method (see `optim`).
custom.optim	a function carrying the MLE optimisation (see details).
weights	an optional vector of weights to be used in the fitting process. Should be `NULL` or a numeric vector. If non-`NULL`, weighted MLE is used, otherwise ordinary MLE.
silent	A logical to remove or show warnings when bootstraping.
...	further arguments passed to the `optim` or `custom.optim` function.

Details

This function is not intended to be called directly but is internally called in fitdist and bootdist when used with the maximum likelihood method and fitdistcens and bootdistcens.

It is assumed that the distr argument specifies the distribution by the probability density function and the cumulative distribution function (d, p). The quantile function and the random generator function (q, r) may be needed by other function such as mmedist, qmedist, mgedist, fitdist,fitdistcens, bootdistcens and bootdist.

For the following named distributions, reasonable starting values will be computed if start is omitted (i.e. NULL) : "norm", "lnorm", "exp" and "pois", "cauchy", "gamma", "logis", "nbinom" (parametrized by mu and size), "geom", "beta", "weibull" from the stats package; "invgamma", "llogis", "invweibull", "pareto1", "pareto" from the actuar package. Note that these starting values may not be good enough if the fit is poor. The function uses a closed-form formula to fit the uniform distribution. If start is a list, then it should be a named list with the same names as in the d,p,q,r functions of the chosen distribution. If start is a function of data, then the function should return a named list with the same names as in the d,p,q,r functions of the chosen distribution.

The mledist function allows user to set a fixed values for some parameters. As for start, if fix.arg is a list, then it should be a named list with the same names as in the d,p,q,r functions of the chosen distribution. If fix.arg is a function of data, then the function should return a named list with the same names as in the d,p,q,r functions of the chosen distribution.

When custom.optim=NULL (the default), maximum likelihood estimations of the distribution parameters are computed with the R base optim. Direct optimization of the log-likelihood is performed (using optim) by default with the "Nelder-Mead" method for distributions characterized by more than one parameter and the "BFGS" method for distributions characterized by only one parameter, or with the method specified in the argument "optim.method" if not "default". Box-constrainted optimization may be used with the method "L-BFGS-B", using the constraints on parameters specified in arguments lower and upper. If non-trivial bounds are supplied, this method will be automatically selected, with a warning. When errors are raised by optim, it's a good idea to start by adding traces during the optimization process by adding control=list(trace=1, REPORT=1).

If custom.optim is not NULL, then the user-supplied function is used instead of the R base optim. The custom.optim must have (at least) the following arguments fn for the function to be optimized, par for the initialized parameters. Internally the function to be optimized will also have other arguments, such as obs with observations and ddistname with distribution name for non censored data (Beware of potential conflicts with optional arguments of custom.optim). It is assumed that custom.optim should carry out a MINIMIZATION. Finally, it should return at least the following components par for the estimate, convergence for the convergence code, value for fn(par) and hessian. See examples in fitdist and fitdistcens.

Optionally, a vector of weights can be used in the fitting process. By default (when weigths=NULL), ordinary MLE is carried out, otherwise the specified weights are used to balance the log-likelihood contributions. It is not yet possible to take into account weighths in functions plotdist, plotdistcens, plot.fitdist, plot.fitdistcens, cdfcomp, cdfcompcens, denscomp, ppcomp, qqcomp, gofstat and descdist (developments planned in the future).

NB: if your data values are particularly small or large, a scaling may be needed before the optimization process. See example (7).

Value

mledist returns a list with following components,

estimate	the parameter estimates.
convergence	an integer code for the convergence of optim defined as below or defined by the user in the user-supplied optimization function. 0 indicates successful convergence. 1 indicates that the iteration limit of optim has been reached. 10 indicates degeneracy of the Nealder-Mead simplex. 100 indicates that optim encountered an internal error.
loglik	the log-likelihood value.
hessian	a symmetric matrix computed by optim as an estimate of the Hessian at the solution found or computed in the user-supplied optimization function. It is used in fitdist to estimate standard errors.
optim.function	the name of the optimization function used for maximum likelihood.
fix.arg	the named list giving the values of parameters of the named distribution that must kept fixed rather than estimated by maximum likelihood or NULL if there are no such parameters.
optim.method	when optim is used, the name of the algorithm used, NULL otherwise.
fix.arg.fun	the function used to set the value of fix.arg or NULL.
weights	the vector of weigths used in the estimation process or NULL.

`mmedist` *Matching moment fit of univariate distributions*

Description

Fit of univariate distributions by matching moments (raw or centered) for non censored data.

Usage

```
mmedist(data, distr, order, memp, start = NULL, fix.arg = NULL, optim.method = "default",
  lower = -Inf, upper = Inf, custom.optim = NULL, weights = NULL, silent = TRUE, ...)
```

Arguments

`data`	A numeric vector for non censored data.
`distr`	A character string `"name"` naming a distribution (see 'details').
`order`	A numeric vector for the moment order(s). The length of this vector must be equal to the number of parameters to estimate.
`memp`	A function implementing empirical moments, raw or centered but has to be consistent with `distr` argument (and `weights` argument). See details below.
`start`	A named list giving the initial values of parameters of the named distribution or a function of data computing initial values and returning a named list. This argument may be omitted (default) for some distributions for which reasonable starting values are computed (see the 'details' section of `mledist`).
`fix.arg`	An optional named list giving the values of fixed parameters of the named distribution or a function of data computing (fixed) parameter values and returning a named list. Parameters with fixed value are thus NOT estimated.
`optim.method`	`"default"` or optimization method to pass to `optim`.
`lower`	Left bounds on the parameters for the `"L-BFGS-B"` method (see `optim`).
`upper`	Right bounds on the parameters for the `"L-BFGS-B"` method (see `optim`).
`custom.optim`	a function carrying the optimization .
`weights`	an optional vector of weights to be used in the fitting process. Should be `NULL` or a numeric vector. If non-`NULL`, weighted MME is used, otherwise ordinary MME.
`silent`	A logical to remove or show warnings when bootstraping.
`...`	further arguments passed to the `optim` or `custom.optim` function.

Details

The argument distr can be one of the base R distributions: "norm", "lnorm", "exp" and "pois", "gamma", "logis", "nbinom" , "geom", "beta" and "unif". In that case, no other arguments than data and distr are required, because the estimate is computed by a closed-form formula. For distributions characterized by one parameter ("geom", "pois" and "exp"), this parameter is simply estimated by matching theoretical and observed means, and for distributions characterized by two parameters, these parameters are estimated by matching theoretical and observed means and variances (Vose, 2000). Note that for these closed-form formula, fix.arg cannot be used and start is ignored.

The argument distr can also be the distribution name as long as a corresponding mdistr function exists, e.g. "pareto" if "mpareto" exists. In that case arguments arguments order and memp have to be supplied in order to carry out the matching numerically, by minimization of the sum of squared differences between observed and theoretical moments. Optionnally other arguments can be supplied to control optimization (see the 'details' section of mledist for details about arguments for the control of optimization). In that case, fix.arg can be used and start is taken into account.

For non closed-form estimators, memp must be provided to compute empirical moments. When weights=NULL, this function must have two arguments x, order: x the numeric vector of the data and order the order of the moment. When weights!=NULL, this function must have three arguments x, order, weights: x the numeric vector of the data, order the order of the moment, weights the numeric vector of weights. See examples below.

Optionally, a vector of weights can be used in the fitting process. By default (when weigths=NULL), ordinary MME is carried out, otherwise the specified weights are used to compute (raw or centered) weighted moments. For closed-form estimators, weighted mean and variance are computed by wtd.mean and wtd.var from the Hmisc package. When a numerical minimization is used, weighted are expected to be computed by the memp function. It is not yet possible to take into account weighths in functions plotdist, plot.fitdist, cdfcomp, denscomp, ppcomp, qqcomp, gofstat and descdist (developments planned in the future).

This function is not intended to be called directly but is internally called in fitdist and bootdist when used with the matching moments method.

Value

mmedist returns a list with following components,

estimate	the parameter estimates.
convergence	(if appropriate) an integer code for the convergence of optim defined as below or defined by the user in the user-supplied optimization function. 0 indicates successful convergence. 1 indicates that the iteration limit of optim has been reached. 10 indicates degeneracy of the Nealder-Mead simplex. 100 indicates that optim encountered an internal error.
loglik	the log-likelihood value.
hessian	(if appropriate) a symmetric matrix computed by optim as an estimate of the Hessian at the solution found or computed in the user-supplied optimization function.
optim.function	(if appropriate) the name of the optimization function.

memp	(if appropriate) the empirical moment function.
order	the order of the moment(s) matched.
method	either "closed formula" or the name of the optimization method.
fix.arg	the named list giving the values of parameters of the named distribution that must kept fixed rather than estimated by maximum likelihood or NULL if there are no such parameters.
optim.method	when optim is used, the name of the algorithm used, NULL otherwise.
weights	the vector of weigths used in the estimation process or NULL.

## End(Not run)
```

`plotdist` *Plot of empirical and theoretical distributions for non-censored data*

Description

Plots an empirical distribution (non-censored data) with a theoretical one if specified.

Usage

```
plotdist(data, distr, para, histo = TRUE, breaks = "default",
  demp = FALSE, discrete, ...)
```

Arguments

`data`	A numeric vector.

distr	A character string "name" naming a distribution for which the corresponding density function dname, the corresponding distribution function pname and the corresponding quantile function qname must be defined, or directly the density function. This argument may be omitted only if para is omitted.
para	A named list giving the parameters of the named distribution. This argument may be omitted only if distr is omitted.
histo	A logical to plot the histogram using the hist function.
breaks	If "default" the histogram is plotted with the function hist with its default breaks definition. Else breaks is passed to the function hist. This argument is not taken into account if discrete is TRUE.
demp	A logical to plot the empirical density on the first plot (alone or superimposed on the histogram depending of the value of the argument histo) using the density function.
discrete	If TRUE, the distribution is considered as discrete. If both distr and discrete are missing, discrete is set to FALSE. If discrete is missing but not distr, discrete is set to TRUE when distr belongs to "binom", "nbinom","geom", "hyper" or "pois".
...	further graphical arguments passed to graphical functions used in plotdist.

Details

Empirical and, if specified, theoretical distributions are plotted in density and in cdf. For the plot in density, the user can use the arguments histo and demp to specify if he wants the histogram using the function hist, the density plot using the function density, or both (at least one of the two arguments must be put to "TRUE"). For continuous distributions, the function hist is used with its default breaks definition if breaks is "default" or passing breaks as an argument if it differs from "default". For continuous distribution and when a theoretical distribution is specified by both arguments distname and para, Q-Q plot (plot of the quantiles of the theoretical fitted distribution (x-axis) against the empirical quantiles of the data) and P-P plot (i.e. for each value of the data set, plot of the cumulative density function of the fitted distribution (x-axis) against the empirical cumulative density function (y-axis)) are also given (Cullen and Frey, 1999). The function ppoints (with default parameter for argument a) is used for the Q-Q plot, to generate the set of probabilities at which to evaluate the inverse distribution. NOTE THAT FROM VERSION 0.4-3, ppoints is also used for P-P plot and cdf plot for continuous data. To personalize the four plots proposed for continuous data, for example to change the plotting position, we recommend the use of functions cdfcomp, denscomp, qqcomp and ppcomp.

plotdist(number,"pois",para=list(lambda=mean(number)))
```

---

plotdistcens *Plot of empirical and theoretical distributions for censored data*

Description

Plots an empirical distribution for censored data with a theoretical one if specified.

Usage

```
plotdistcens(censdata, distr, para, leftNA = -Inf, rightNA = Inf,
    Turnbull = TRUE, Turnbull.confint = FALSE, ...)
```

Arguments

censdata	A dataframe of two columns respectively named left and right, describing each observed value as an interval. The left column contains either NA for left censored observations, the left bound of the interval for interval censored observations, or the observed value for non-censored observations. The right column contains either NA for right censored observations, the right bound of the interval for interval censored observations, or the observed value for non-censored observations.
distr	A character string "name" naming a distribution, for which the corresponding density function dname and the corresponding distribution function pname must be defined, or directly the density function.
para	A named list giving the parameters of the named distribution. This argument may be omitted only if distr is omitted.
leftNA	the real value of the left bound of left censored observations : -Inf or a finite value such as 0 for positive data for example.
rightNA	the real value of the right bound of right censored observations : Inf or a finite value such as a realistic maximum value.
Turnbull	if TRUE the Turnbull algorithm is used to estimate the cdf curve of the censored data and previous arguments leftNA and rightNA are not used (see details)
Turnbull.confint	if TRUE confidence intervals will be added to the Turnbull plot.
...	further graphical arguments passed to other methods

Details

Empirical and, if specified, theoretical distributions are plotted in cdf. If Turnbull is TRUE, the EM approach of Turnbull (Turnbull, 1974) is used to compute the overall empirical cdf curve, with confidence intervals if Turnbull.confint is TRUE, by calls to functions survfit and plot.survfit from the survival package.

Else data are reported directly as segments for interval, left and right censored data, and as points for non-censored data. Before plotting, observations are ordered and a rank r is associated to each of them. Left censored observations are ordered first, by their right bounds. Interval censored and non censored observations are then ordered by their mid-points and, at last, right censored observations are ordered by their left bounds. If leftNA (resp. rightNA) is finite, left censored (resp. right censored) observations are considered as interval censored observations and ordered by mid-points with non-censored and interval censored data. It is sometimes necessary to fix rightNA or leftNA to a realistic extreme value, even if not exactly known, to obtain a reasonable global ranking of

observations. After ranking, each of the n observations is plotted as a point (one x-value) or a segment (an interval of possible x-values), with an y-value equal to r/n, r being the rank of each observation in the global ordering previously described. This second method may be interesting but is certainly less rigorous than the Turnbull method that should be prefered.

qmedist *Quantile matching fit of univariate distributions*

Description

Fit of univariate distribution by matching quantiles for non censored data.

Usage

```
qmedist(data, distr, probs, start = NULL, fix.arg = NULL, qtype = 7,
    optim.method = "default", lower = -Inf, upper = Inf,
    custom.optim = NULL, weights = NULL, silent = TRUE, ...)
```

Arguments

data	A numeric vector for non censored data.
distr	A character string "name" naming a distribution for which the corresponding quantile function qname and the corresponding density distribution dname must be classically defined.
probs	A numeric vector of the probabilities for which the quantile matching is done. The length of this vector must be equal to the number of parameters to estimate.
start	A named list giving the initial values of parameters of the named distribution or a function of data computing initial values and returning a named list. This argument may be omitted (default) for some distributions for which reasonable starting values are computed (see the 'details' section of mledist).
fix.arg	An optional named list giving the values of fixed parameters of the named distribution or a function of data computing (fixed) parameter values and returning a named list. Parameters with fixed value are thus NOT estimated.
qtype	The quantile type used by the R quantile function to compute the empirical quantiles, (default 7 corresponds to the default quantile method in R).
optim.method	"default" or optimization method to pass to optim.
lower	Left bounds on the parameters for the "L-BFGS-B" method (see optim).
upper	Right bounds on the parameters for the "L-BFGS-B" method (see optim).
custom.optim	a function carrying the optimization.
weights	an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If non-NULL, weighted QME is used, otherwise ordinary QME.
silent	A logical to remove or show warnings when bootstraping.
...	further arguments passed to the optim or custom.optim function.

Details

The qmedist function carries out the quantile matching numerically, by minimization of the sum of squared differences between observed and theoretical quantiles. The optimization process is the same as mledist, see the 'details' section of mledist.

Optionally, a vector of weights can be used in the fitting process. By default (when weigths=NULL), ordinary QME is carried out, otherwise the specified weights are used to compute weighted quantiles used in the squared differences. Weigthed quantiles are computed by wtd.quantile from the Hmisc package. It is not yet possible to take into account weighths in functions plotdist, plot.fitdist, cdfcomp, denscomp, ppcomp, qqcomp, gofstat and descdist (developments planned in the future).

This function is not intended to be called directly but is internally called in fitdist and bootdist.

Value

qmedist returns a list with following components,

estimate	the parameter estimates.
convergence	an integer code for the convergence of optim defined as below or defined by the user in the user-supplied optimization function. 0 indicates successful convergence. 1 indicates that the iteration limit of optim has been reached. 10 indicates degeneracy of the Nealder-Mead simplex. 100 indicates that optim encountered an internal error.
value	the value of the statistic distance corresponding to estimate.
hessian	a symmetric matrix computed by optim as an estimate of the Hessian at the solution found or computed in the user-supplied optimization function.
probs	the probability vector on which quantiles are matched.
optim.function	the name of the optimization function used.
loglik	the log-likelihood.
fix.arg	the named list giving the values of parameters of the named distribution that must kept fixed rather than estimated by maximum likelihood or NULL if there are no such parameters.
optim.method	when optim is used, the name of the algorithm used, NULL otherwise.
fix.arg.fun	the function used to set the value of fix.arg or NULL.
weights	the vector of weigths used in the estimation process or NULL.

quantiles *Quantile estimation from a fitted distribution*

Description

Quantile estimation from a fitted distribution, optionally with confidence intervals calculated from the bootstrap result.

Usage

```
## S3 method for class 'fitdist'
quantile(x, probs = seq(0.1, 0.9, by=0.1), ...)
## S3 method for class 'fitdistcens'
quantile(x, probs = seq(0.1, 0.9, by=0.1), ...)
## S3 method for class 'bootdist'
quantile(x, probs = seq(0.1, 0.9, by=0.1),CI.type = "two.sided",
  CI.level = 0.95, ...)
## S3 method for class 'bootdistcens'
quantile(x, probs = seq(0.1, 0.9, by=0.1),CI.type = "two.sided",
  CI.level = 0.95, ...)
## S3 method for class 'quantile.fitdist'
print(x, ...)
## S3 method for class 'quantile.fitdistcens'
print(x, ...)
## S3 method for class 'quantile.bootdist'
print(x, ...)
## S3 method for class 'quantile.bootdistcens'
print(x, ...)
```

Arguments

x	An object of class "fitdist", "fitdistcens", "bootdist", "bootdistcens" or "quantile.fitdist", "quantile.fitdistcens", "quantile.bootdist", "quantile.bootdistcens" for the print generic function.
probs	A numeric vector of probabilities with values in [0, 1] at which quantiles must be calculated.
CI.type	Type of confidence intervals : either "two.sided" or one-sided intervals ("less" or "greater").
CI.level	The confidence level.
...	Further arguments to be passed to generic functions.

Details

Quantiles of the parametric distribution are calculated for each probability specified in probs, using the estimated parameters. When used with an object of class "bootdist" or "bootdistcens", percentile confidence intervals and medians etimates are also calculated from the bootstrap result. If CI.type is two.sided, the CI.level two-sided confidence intervals of quantiles are calculated. If CI.type is less or greater, the CI.level one-sided confidence intervals of quantiles are calculated. The print functions show the estimated quantiles with percentile confidence intervals and

median estimates when a bootstrap resampling has been done previously, and the number of bootstrap iterations for which the estimation converges if it is inferior to the whole number of bootstrap iterations.

Value

`quantile` returns a list with 2 components (the first two described below) when called with an object of class `"fitdist"` or `"fitdistcens"` and 8 components (described below) when called with an object of class `"bootdist"` or `"bootdistcens"` :

`quantiles`	a dataframe containing the estimated quantiles for each probability value specified in the argument `probs` (one row, and as many columns as values in `probs`).
`probs`	the numeric vector of probabilities at which quantiles are calculated.
`bootquant`	A data frame containing the bootstraped values for each quantile (many rows, as specified in the call to `bootdist` in the argument `niter`, and as many columns as values in `probs`)
`quantCI`	If `CI.type` is `two.sided`, the two bounds of the `CI.level` percent two.sided confidence interval for each quantile (two rows and as many columns as values in `probs`). If `CI.type` is `less`, right bound of the `CI.level` percent one.sided confidence interval for each quantile (one row). If `CI.type` is `greater`, left bound of the `CI.level` percent one.sided confidence interval for each quantile (one row).
`quantmedian`	Median of bootstrap estimates (per probability).
`CI.type`	Type of confidence interval: either `"two.sided"` or one-sided intervals (`"less"` or `"greater"`).
`CI.level`	The confidence level.
`nbboot`	The number of samples drawn by bootstrap.
`nbconverg`	The number of iterations for which the optimization algorithm converges.

salinity *Species-Sensitivity Distribution (SSD) for salinity tolerance*

Description

72-hour acute salinity tolerance (LC50 values) of riverine macro-invertebrates.

Usage

```
data(salinity)
```

Format

`salinity` is a data frame with 2 columns named left and right, describing each observed LC50 value (in electrical condutivity, millisiemens per centimeter) as an interval. The left column contains either NA for left censored observations, the left bound of the interval for interval censored observations, or the observed value for non-censored observations. The right column contains either NA for right censored observations, the right bound of the interval for interval censored observations, or the observed value for noncensored observations.

`smokedfish` *Contamination data of Listeria monocytogenes in smoked fish*

Description

Contamination data of *Listeria monocytogenes* in smoked fish on the Belgian market in the period 2005 to 2007.

Usage

```
data(smokedfish)
```

Format

`smokedfish` is a data frame with 2 columns named left and right, describing each observed value of *Listeria monocytogenes* concentration (in CFU/g) as an interval. The left column contains either NA for left censored observations, the left bound of the interval for interval censored observations, or the observed value for non-censored observations. The right column contains either NA for right censored observations, the right bound of the interval for interval censored observations, or the observed value for non-censored observations.
