Version 2.3.2

Date 2016-02-24

Title Estimation and Use of the Generalised (Tukey) Lambda Distribution

Suggests lmom

Imports stats, graphics, e1071

Author Robert King <Robert.King@newcastle.edu.au>, Benjamin Dean <Benjamin.Dean@uon.edu.au>, Sigbert Klinke

Maintainer Robert King <Robert.King@newcastle.edu.au>

Description The generalised lambda distribution, or Tukey lambda distribution, provides a wide variety of shapes with one functional form.

This package provides random numbers, quantiles, probabilities, densities and density quantiles for four different parameterisations of the distribution.

It provides the density function, distribution function, and Quantile-Quantile plots.

It implements a variety of estimation methods for the distribution, including diagnostic plots.

Estimation methods include the starship (all 4 parameterisations) and a number of methods for only the FKML parameterisation.

These include maximum likelihood, maximum product of spacings, Titterington's method, Moments, L-Moments, Trimmed L-Moments and Distributional Least Absolutes.

fit.fkml	<i>Estimate parameters of the FKML parameterisation of the generalised lambda distribution</i>
----------	--

Description

Estimates parameters of the FKML parameterisation of the Generalised λ Distribution. Five estimation methods are available; Numerical Maximum Likelihood, Maximum Product of Spacings, Titterington's Method, the Starship (also available in the [starship](#) function, which uses the same underlying code as this for the fkml parameterisation), and Trimmed L-Moments.

Usage

```
fit.fkml(x, method = "ML", t1 = 0, t2 = 0,
  l3.grid = c(-0.9, -0.5, -0.1, 0, 0.1, 0.2, 0.4, 0.8, 1, 1.5),
  l4.grid = l3.grid, record.cpu.time = TRUE, optim.method = "Nelder-Mead",
  inverse.eps = .Machine$double.eps, optim.control=list(maxit=10000),
  optim.penalty=1e20, return.data=FALSE)
```

Arguments

x	Data to be fitted, as a vector
method	A character string, to select the estimation method. One of: ML for Numerical Maximum Likelihood, MPS or MSP for Maximum Product of Spacings, TM for Titterington's Method, SM for Starship Method, TL for Method of TL-moments, or DLA for the method of distributional least absolutes.
t1	Number of observations to be trimmed from the left in the conceptual sample, t_1 (A non-negative integer, only used by TL-moment estimation, see details section)
t2	Number of observations to be trimmed from the right in the conceptual sample, t_2 (A non-negative integer, only used by TL-moment estimation, see details section). These two arguments are restricted by $t_1 + t_2 < n$, where n is the sample size

13.grid	A vector of values to form the grid of values of λ_3 used to find a starting point for the optimisation.
14.grid	A vector of values to form the grid of values of λ_4 used to find a starting point for the optimisation.
record.cpu.time	Boolean — should the CPU time used in fitting be recorded in the fitted model object?
optim.method	Optimisation method, use any of the options available under method of <code>optim</code> .
inverse.eps	Accuracy of calculation for the numerical determination of $F(x)$, defaults to <code>.Machine\$double.eps</code> .
optim.control	List of options for the optimisation step. See <code>optim</code> for details.
optim.penalty	The penalty to be added to the objective function if parameter values are proposed outside the allowed region
return.data	Logical: Should the function return the data (from the argument data)?

Details

Maximum Likelihood Estimation of the generalised lambda distribution (`gld`) proceeds by calculating the density of the data for candidate values of the parameters. Because the `gld` is defined by its quantile function, the method first numerically obtains $F(x)$ by inverting $Q(u)$, then obtains the density for that observation.

Maximum Product of Spacings estimation (sometimes referred to as Maximum Spacing Estimation, or Maximum Spacings Product) finds the parameter values that maximise the product of the spacings (the difference between successive depths, $F_\theta(x_{(i+1)}) - F_\theta(x_{(i)})$, where $F_\theta(x)$ is the distribution function for the candidate values of the parameters). See Dean (2013) and Cheng & Amin (1981) for details.

Titterton (1985) remarked that MPS effectively added an “extra observation”; there are N data points in the original sample, but $N + 1$ spacings in the expression maximised in MPS. Instead of using spacings between transformed data points, so method `TM` uses spacings between transformed, adjacently-averaged, data points. The spacings are given by $D_i = F_\theta(z_{(i)}) - F_\theta(z_{(i-1)})$, where $\alpha_1 = z_0 < z_1 < \dots < z_n = \alpha_2$ and $z_i = (x_{(i)} + x_{(i+1)})/2$ for $i = 1, 2, \dots, n-1$ (where α_1 and α_2 are the lower and upper bounds on the support of the distribution). This reduces the number of spacings to n and achieves concordance with the original sample size. See Titterton (1985) and Dean (2013) for details.

The starship is built on the fact that the `gld` is a transformation of the uniform distribution. Thus the inverse of this transformation is the distribution function for the `gld`. The starship method applies different values of the parameters of the distribution to the distribution function, calculates the depths q corresponding to the data and chooses the parameters that make these calculated depths closest (as measured by the Anderson-Darling statistic) to a uniform distribution. See King & MacGillivray (1999) for details.

TL-Moment estimation chooses the values of the parameters that minimise the difference between the sample Trimmed L-Moments of the data and the Trimmed L-Moments of the fitted distribution. TL-Moments are based on inflating the conceptual sample size used in the definition of L-Moments. The `t1` and `t2` arguments to the function define the extent of trimming of the conceptual sample. Thus, the default values of `t1=0` and `t2=0` reduce the TL-Moment method to L-Moment estimation.

t_1 and t_2 give the number of observations to be trimmed (from the left and right respectively) from the conceptual sample of size $n + t_1 + t_2$. These two arguments should be non-negative integers, and $t_1 + t_2 < n$, where n is the sample size. See Elamir and Seheult (2003) for more on TL-Moments in general, Asquith, (2007) for TL-Moments of the RS parameterisation of the gld and Dean (2013) for more details on TL-Moment estimation of the gld.

The method of distributional least absolutes (DLA) minimises the sum of absolute deviations between the order statistics and their medians (based on the candidate parameters). See Dean (2013) for more information.

Value

`fit.fkml` returns an object of class "starship" (regardless of the estimation method used).

`print` prints the estimated values of the parameters, while `summary.starship` prints these by default, but can also provide details of the estimation process (from the components `grid.results`, `data` and `optim` detailed below).

The value of `fit.fkml` is a list containing the following components:

<code>lambda</code>	A vector of length 4, giving the estimated parameters, in order, λ_1 - location parameter λ_2 - scale parameter λ_3 - first shape parameter λ_4 - second shape parameter
<code>grid.results</code>	output from the grid search
<code>optim</code>	output from the optim search, <code>optim</code> for details
<code>cpu</code>	A vector showing the computing time used, returned if <code>record.cpu.time</code> is TRUE
<code>data</code>	The data, if <code>return.data</code> is TRUE

fit.fkml.moments.val *Method of moments estimation for the FKML type of the generalised lambda distribution using given moment values*

Description

Estimates parameters of the generalised lambda distribution (FKML type) using the Method of Moments on the basis of moment values (mean, variance, skewness ratio and kurtosis ratio (note, not the *excess kurtosis*)).

Usage

```
fit.fkml.moments.val(moments=c(mean=0, variance=1, skewness=0,
  kurtosis=3), optim.method="Nelder-Mead", optim.control= list(),
  starting.point = c(0,0))
```

Arguments

moments A vector of length 4, consisting of the mean, variance and moment ratios for skewness and kurtosis

optim.method Optimisation method for [optim](#) to use, defaults to Nelder-Mead

optim.control argument control, passed to [optim](#).

starting.point a vector of length 2, giving the starting value for λ_3 and λ_4 .

Details

Estimates parameters of the generalised lambda distribution (FKML type) using Method of Moments on the basis of moment values (mean, variance, skewness ratio and kurtosis ratio). Note this is the fourth central moment divided by the second central moment, without subtracting 3. `fit.fkml.moments` (to come in version 2.4 of the `gld` package) will estimate using the method of moments for a dataset, including calculating the sample moments. This function uses [optim](#) to find the parameters that minimise the sum of squared differences between the skewness and kurtosis sample ratios and their counterpart expressions for those ratios on the basis of the parameters λ_3 and λ_4 . On the basis of these estimates (and the mean and variance), this function then estimates $\hat{\lambda}_2$ and then $\hat{\lambda}_1$.

Note that the first 4 moments don't uniquely identify members of the generalised λ distribution. Typically, for a set of moments that correspond to a unimodal gld, there is another set of parameters that give a distribution with the same first 4 moments. This other distribution has a truncated appearance (that is it is on finite support and the density is non-zero at the end points). See the examples below.

Value

A vector containing the parameters of the FKML type generalised lambda; λ_1 - location parameter λ_2 - scale parameter λ_3 - first shape parameter λ_4 - second shape parameter (See [gld](#) for more details)

 GeneralisedLambdaDistribution

The Generalised Lambda Distribution

Description

Density, density quantile, distribution function, quantile function and random generation for the generalised lambda distribution (also known as the asymmetric lambda, or Tukey lambda). Provides for four different parameterisations, the fkm1 (recommended), the rs, the gpd and a five parameter version of the FMKL, the fm5.

Usage

```

dgl(x, lambda1 = 0, lambda2 = NULL, lambda3 = NULL, lambda4 = NULL,
    param = "fkm1", lambda5 = NULL, inverse.eps = .Machine$double.eps,
    max.iterations = 500)
dqgl(p, lambda1, lambda2 = NULL, lambda3 = NULL, lambda4 = NULL,
    param = "fkm1", lambda5 = NULL)
pql(q, lambda1 = 0, lambda2 = NULL, lambda3 = NULL, lambda4 = NULL,
    param = "fkm1", lambda5 = NULL, inverse.eps = .Machine$double.eps,
    max.iterations = 500)
qgl(p, lambda1, lambda2 = NULL, lambda3 = NULL, lambda4 = NULL,
    param = "fkm1", lambda5 = NULL)
rgl(n, lambda1=0, lambda2 = NULL, lambda3 = NULL, lambda4 = NULL,
    param = "fkm1", lambda5 = NULL)
  
```

Arguments

x, q	vector of quantiles.
p	vector of probabilities.
n	number of observations.
lambda1	This can be either a single numeric value or a vector. If it is a vector, it must be of length 4 for parameterisations fkm1, rs and gpd and of length 5 for parameterisation fm5. If it is a vector, it gives all the parameters of the generalised lambda distribution (see below for details) and the other lambda arguments must be left as NULL. If it is a a single value, it is λ_1 , the location parameter of the distribution (α for the gpd parameterisation). The other parameters are given by the following arguments <i>Note that the numbering of the λ parameters for the fkm1 parameterisation is different to that used by Freimer, Mudholkar, Kollia and Lin. Note also that in the gpd parameterisation, the four parameters are labelled $\alpha, \beta, \delta, \lambda$.</i>
lambda2	λ_2 - scale parameter (β for gpd)
lambda3	λ_3 - first shape parameter (δ , a skewness parameter for gpd)
lambda4	λ_4 - second shape parameter (λ , a tail-shape parameter for gpd)

lambda5	λ_5 - a skewing parameter, in the fm5 parameterisation
param	choose parameterisation (see below for details) fmk1 uses <i>Freimer, Mudholkar, Kollia and Lin (1988)</i> (default). rs uses <i>Ramberg and Schmeiser (1974)</i> gpd uses GPD parameterisation, see van Staden and Loots (2009) fm5 uses the 5 parameter version of the FMKL parameterisation (paper to appear)
inverse.eps	Accuracy of calculation for the numerical determination of $F(x)$, defaults to <code>.Machine\$double.eps</code>
max.iterations	Maximum number of iterations in the numerical determination of $F(x)$, defaults to 500

Details

The generalised lambda distribution, also known as the asymmetric lambda, or Tukey lambda distribution, is a distribution with a wide range of shapes. The distribution is defined by its quantile function ($Q(u)$), the inverse of the distribution function. The `gld` package implements three parameterisations of the distribution. The default parameterisation (the FMKL) is that due to *Freimer, Mudholkar, Kollia and Lin (1988)* (see references below), with a quantile function:

$$Q(u) = \lambda_1 + \frac{\frac{u^{\lambda_3} - 1}{\lambda_3} - \frac{(1-u)^{\lambda_4} - 1}{\lambda_4}}{\lambda_2}$$

for $\lambda_2 > 0$.

A second parameterisation, the RS, chosen by setting `param="rs"` is that due to *Ramberg and Schmeiser (1974)*, with the quantile function:

$$Q(u) = \lambda_1 + \frac{u^{\lambda_3} - (1-u)^{\lambda_4}}{\lambda_2}$$

This parameterisation has a complex series of rules determining which values of the parameters produce valid statistical distributions. See [gl.check.lambda](#) for details.

Another parameterisation, the GPD, chosen by setting `param="gpd"` is due to van Staden and Loots (2009), with a quantile function:

$$Q(u) = \alpha + \beta \left((1-\delta) \frac{(u^\lambda - 1)}{\lambda} - \delta \frac{((1-u)^\lambda - 1)}{\lambda} \right)$$

for $\beta > 0$ and $-1 \leq \delta \leq 1$. (where the parameters appear in the `par` argument to the function in the order $\alpha, \beta, \delta, \lambda$). This parameterisation has simpler L-moments than other parameterisations and δ is a skewness parameter and λ is a tailweight parameter.

Another parameterisation, the FM5, chosen by setting `param="fm5"` adds an additional skewing parameter to the FMKL parameterisation. This uses the same approach as that used by Gilchrist (2000) for the RS parameterisation. The quantile function is

$$F^{-1}(u) = \lambda_1 + \frac{\frac{(1-\lambda_5)(u^{\lambda_3} - 1)}{\lambda_3} - \frac{(1+\lambda_5)((1-u)^{\lambda_4} - 1)}{\lambda_4}}{\lambda_2}$$

for $\lambda_2 > 0$ and $-1 \leq \lambda_5 \leq 1$.

The distribution is defined by its quantile function and its distribution and density functions do not exist in closed form. Accordingly, the results from `pgl` and `dgl` are the result of numerical solutions to the quantile function, using the Newton-Raphson method. Since the density quantile function, $f(F^{-1}(u))$, does exist, an additional function, `dqgl`, computes this.

The functions `qdgl.fmk1`, `qdgl.rs`, `qdgl.fm5`, `qgl.fmk1`, `qgl.rs` and `qgl.fm5` from versions 1.5 and earlier of the `gld` package have been renamed (and hidden) to `.qdgl.fmk1`, `.qdgl.rs`, `.qdgl.fm5`, `.qgl.fmk1`, `.qgl.rs` and `.qgl.fm5` respectively. See the code for more details

Value

`dgl` gives the density (based on the quantile density and a numerical solution to $F^{-1}(u) = x$),

`qdgl` gives the quantile density,

`pgl` gives the distribution function (based on a numerical solution to $F^{-1}(u) = x$),

`qgl` gives the quantile function, and

`rgl` generates random deviates.

# calculate the probabilities more accurately than normal
```

gl.check.lambda	<i>Function to check the validity of parameters of the generalized lambda distribution</i>
-----------------	--

Description

Checks the validity of parameters of the generalized lambda. The tests are simple for the FMKL and FM5 parameterisations, and much more complex for the RS parameterisation.

Usage

```
gl.check.lambda(lambdas, lambda2 = NULL, lambda3 = NULL, lambda4 = NULL, param = "fkm1",
               lambda5 = NULL, vect = FALSE)
```

Arguments

lambdas	This can be either a single numeric value or a vector. If it is a vector, it must be of length 4 for parameterisations fkm1 or rs and of length 5 for parameterisation fm5. If it is a vector, it gives all the parameters of the generalised lambda distribution (see below for details) and the other lambda arguments must be left as NULL. If it is a single value, it is λ_1 , the location parameter of the distribution and the other parameters are given by the following arguments <i>Note that the numbering of the λ parameters for the fkm1 parameterisation is different to that used by Freimer, Mudholkar, Kollia and Lin.</i>
lambda2	λ_2 - scale parameter
lambda3	λ_3 - first shape parameter
lambda4	λ_4 - second shape parameter
lambda5	λ_5 - a skewing parameter, in the fm5 parameterisation
param	choose parameterisation: fkm1 uses <i>Freimer, Mudholkar, Kollia and Lin (1988)</i> (default). rs uses <i>Ramberg and Schmeiser (1974)</i> fm5 uses the 5 parameter version of the FMKL parameterisation (paper to appear)
vect	A logical, set this to TRUE if the parameters are given in the vector form (it turns off checking of the format of lambdas and the other lambda arguments)

Details

See [GeneralisedLambdaDistribution](#) for details on the generalised lambda distribution. This function determines the validity of parameters of the distribution.

The FMKL parameterisation gives a valid statistical distribution for any real values of $\lambda_1, \lambda_3, \lambda_4$ and any positive real values of λ_2 .

The FM5 parameterisation gives statistical distribution for any real values of $\lambda_1, \lambda_3, \lambda_4$, any positive real values of λ_2 and values of λ_5 that satisfy $-1 \leq \lambda_5 \leq 1$.

For the RS parameterisation, the combinations of parameters value that give valid distributions are the following (the region numbers in the table correspond to the labelling of the regions in *Ramberg and Schmeiser (1974)* and *Karian, Dudewicz and McDonald (1996)*):

region	λ_1	λ_2	λ_3	λ_4	note
1	all	< 0	< -1	> 1	
2	all	< 0	> 1	< -1	
3	all	> 0	≥ 0	≥ 0	one of λ_3 and λ_4 must be non-zero
4	all	< 0	≤ 0	≤ 0	one of λ_3 and λ_4 must be non-zero
5	all	< 0	> -1 and < 0	> 1	equation 1 below must also be satisfied
6	all	< 0	> 1	> -1 and < 0	equation 2 below must also be satisfied

Equation 1

$$\frac{(1 - \lambda_3)^{1-\lambda_3} (\lambda_4 - 1)^{\lambda_4-1}}{(\lambda_4 - \lambda_3)^{\lambda_4-\lambda_3}} < -\frac{\lambda_3}{\lambda_4}$$

Equation 2

$$\frac{(1 - \lambda_4)^{1-\lambda_4} (\lambda_3 - 1)^{\lambda_3-1}}{(\lambda_3 - \lambda_4)^{\lambda_3-\lambda_4}} < -\frac{\lambda_4}{\lambda_3}$$

Value

This logical function takes on a value of TRUE if the parameter values given produce a valid statistical distribution and FALSE if they don't

Note

The complex nature of the rules in this function for the RS parameterisation are the reason for the invention of the FMKL parameterisation and its status as the default parameterisation in the other generalized lambda functions.

```

gld-Deprecated	<i>Deprecated functions</i>
----------------	-----------------------------

Description

qdgl: This calculates the density quantile function of the GLD, so it has been renamed [dqgl](#).

gld.moments	<i>Calculate moments of the FKML type of the generalised lambda distribution for given parameter values</i>
-------------	---

Description

Calculates the mean, variance, skewness ratio and kurtosis ratio of the generalised λ distribution for given parameter values.

Usage

```
gld.moments(par, type="fkml", ratios=TRUE)
```

Arguments

par	A vector of length 4, giving the parameters of the generalised lambda distribution, consisting of; λ_1 location parameter λ_2 - scale parameter λ_3 - first shape parameter λ_4 - second shape parameter
type	choose the type of generalised lambda distribution. Currently gld.moments only supports fkml which uses <i>Freimer, Kollia, Mudholkar, and Lin (1988)</i> (default).
ratios	Logical. TRUE to give moment ratios for skewness and kurtosis, FALSE to give the third and fourth central moments instead.

Details

The FKML type of the generalised λ distribution was introduced by Freimer et al (1988) who gave expressions for the moments. In the limit, as the shape parameters (λ_3 and λ_4) go to zero, the distribution is defined using limit results. The moments in these limiting cases were given by van Staden (2013). This function calculates the first 4 moments.

See pages 96–97 of van Staden (2013) for the full expressions for these moments.

Value

A vector containing the first four moments of the FKML type generalized lambda. If `ratio` is true, the vector contains the mean, variance, skewness ratio and kurtosis ratio. If `ratio` is false, the vector contains the mean, variance, third central moment and fourth central moment.

plot.starship

Plots to compare a fitted generalised lambda distribution to data

Description

Plots to compare a Generalised Lambda Distribution fitted via the [starship](#) to data

Usage

```
## S3 method for class 'starship'
plot(x, data, ask = FALSE, one.page = TRUE,
     breaks = "Sturges", histogram.title = NULL,...)
```

Arguments

x	An object of class starship .
data	Data to which the gld was fitted. Leave this as NULL if the return.data argument was TRUE in the starship call that created x.
ask	Ask for user input before next plot — passed to par (ask). Does not permanently change this setting. Ignored if one.page is TRUE
one.page	Put the two plots on one page using par (mfrow=c(2,1)). Does not permanently change this setting.
breaks	Control the number of histogram bins — passed to hist .
histogram.title	Main title for histogram — passed to hist (main=).
...	arguments passed to plot AND hist

Details

`summary` Gives the details of the [starship.adaptivegrid](#) and `optim` steps.

plotgl	<i>Plots of density and distribution function for the generalised lambda distribution</i>
--------	---

Description

Produces plots of density and distribution function for the generalised lambda distribution. Although you could use `plot(function(x)dgl(x))` to do this, the fact that the density and quantiles of the generalised lambda are defined in terms of the depth, u , means that a separate function that uses the depths to produce the values to plot is more efficient

Usage

```
plotgld(lambda1 = 0, lambda2 = NULL, lambda3 = NULL, lambda4 = NULL,
  param = "fmk1", lambda5 = NULL, add = NULL, truncate = 0,
  bnw = FALSE, col.or.type = 1, granularity = 10000, xlab = "x",
  ylab = NULL, quant.probs = seq(0,1,.25), new.plot = NULL, ...)
plotglc(lambda1 = 0, lambda2 = NULL, lambda3 = NULL, lambda4 = NULL,
  param = "fmk1", lambda5 = NULL, granularity = 10000, xlab = "x",
  ylab = "cumulative probability", add = FALSE, ...)
```

Arguments

lambda1	This can be either a single numeric value or a vector. If it is a vector, it must be of length 4 for parameterisations fmk1 or rs and of length 5 for parameterisation fm5. If it is a vector, it gives all the parameters of the generalised lambda distribution (see below for details) and the other lambda arguments must be left as NULL. If it is a single value, it is λ_1 , the location parameter of the distribution and the other parameters are given by the following arguments <i>Note that the numbering of the λ parameters for the fmk1 parameterisation is different to that used by Freimer, Mudholkar, Kollia and Lin.</i>
lambda2	λ_2 - scale parameter
lambda3	λ_3 - first shape parameter
lambda4	λ_4 - second shape parameter
lambda5	λ_5 - a skewing parameter, in the fm5 parameterisation
param	choose parameterisation: fmk1 uses <i>Freimer, Mudholkar, Kollia and Lin (1988)</i> (default). rs uses <i>Ramberg and Schmeiser (1974)</i> fm5 uses the 5 parameter version of the FMKL parameterisation (paper to appear)
add	a logical value describing whether this should add to an existing plot (using lines) or produce a new plot (using plot). Defaults to FALSE (new plot) if both add and new.plot are NULL.
truncate	for plotgld, a minimum density value at which the plot should be truncated.

bnw	a logical value, true for a black and white plot, with different densities identified using line type (lty), false for a colour plot, with different densities identified using line colour (col)
col.or.type	Colour or type of line to use
granularity	Number of points to calculate quantiles and density at — see <i>details</i>
xlab	X axis label
ylab	Y axis label
quant.probs	Quantiles of distribution to return (see <i>value</i> below). Set to NULL to suppress this return entirely.
new.plot	a logical value describing whether this should produce a new plot (using plot), or add to an existing plot (using lines). Ignored if add is set.
...	arguments that get passed to plot if this is a new plot

Details

The generalised lambda distribution is defined in terms of its quantile function. The density of the distribution is available explicitly as a function of depths, u , but not explicitly available as a function of x . This function calculates quantiles and depths as a function of depths to produce a density plot `plotgld` or cumulative probability plot `plotglc`.

The plot can be truncated, either by restricting the values using `xlim` — see `par` for details, or by the `truncate` argument, which specifies a minimum density. This is recommended for graphs of densities where the tail is very long.

Value

A number of quantiles from the distribution, the default being the minimum, maximum and quartiles.

qdgl-deprecated

Deprecated function for density quantile function of gld. See qdgl instead

Description

See qdgl help instead.

Usage

```
qdgl(p, lambda1, lambda2 = NULL, lambda3 = NULL, lambda4 = NULL,
param = "fkml", lambda5 = NULL)
```

Arguments

p	See qdgl help instead.
lambda1	See qdgl help instead.
lambda2	See qdgl help instead.
lambda3	See qdgl help instead.
lambda4	See qdgl help instead.
param	See qdgl help instead.
lambda5	See qdgl help instead.

Value

See qdgl help instead.

qqgl *Quantile-Quantile plot against the generalised lambda distribution*

Description

qqgl produces a Quantile-Quantile plot of data against the generalised lambda distribution, or a Q-Q plot to compare two sets of parameter values for the generalised lambda distribution. It does for the generalised lambda distribution what [qqnorm](#) does for the normal.

Usage

```
qqgl(y = NULL, lambda1 = 0, lambda2 = NULL, lambda3 = NULL, lambda4 = NULL,
     param = "fkm1", lambda5 = NULL, abline = TRUE, lambda.pars1 = NULL, lambda.pars2 = NULL,
     param2 = "fkm1", points.for.2.param.sets = 4000, ...)
```

Arguments

y	The data sample
lambda1	This can be either a single numeric value or a vector. If it is a vector, it must be of length 4 for parameterisations fkm1 or rs and of length 5 for parameterisation fm5. If it is a vector, it gives all the parameters of the generalised lambda distribution (see below for details) and the other lambda arguments must be left as NULL. Alternatively, leave lambda1 as the default value of 0 and use the lambda.pars1 argument instead. If it is a single value, it is λ_1 , the location parameter of the distribution and the other parameters are given by the following arguments <i>Note that the numbering of the λ parameters for the fkm1 parameterisation is different to that used by Freimer, Mudholkar, Kollia and Lin.</i>
lambda2	λ_2 - scale parameter
lambda3	λ_3 - first shape parameter

lambda4	λ_4 - second shape parameter
lambda5	λ_5 - a skewing parameter, in the fm5 parameterisation
param	choose parameterisation: fmk1 uses <i>Freimer, Mudholkar, Kollia and Lin (1988)</i> (default). rs uses <i>Ramberg and Schmeiser (1974)</i> fm5 uses the 5 parameter version of the FMKL parameterisation (paper to appear)
abline	A logical value, TRUE adds a line through the origin with a slope of 1 to the plot
lambda.pars1	Parameters of the generalised lambda distribution (see lambda1 to lambda4 for details).
lambda.pars2	Second set of parameters of the generalised lambda distribution (see lambda1 to lambda4 for details. Use lambda.pars1 and lambda.pars2 to produce a QQ plot comparing two generalised lambda distributions
param2	parameterisation to use for the second set of parameter values
points.for.2.param.sets	Number of quantiles to use in a Q-Q plot comparing two sets of parameter values
...	graphical parameters, passed to qqplot

Details

See [gld](#) for more details on the Generalised Lambda Distribution. A Q-Q plot provides a way to visually assess the correspondence between a dataset and a particular distribution, or between two distributions.

Value

A list of the same form as that returned by [qqline](#)

x	The x coordinates of the points that were/would be plotted, corresponding to a generalised lambda distribution with parameters $\lambda_1, \lambda_2, \lambda_3, \lambda_4$.
y	The original y vector, i.e., the corresponding y coordinates, or a corresponding set of quantiles from a generalised lambda distribution with the second set of parameters

```

starship	<i>Carry out the “starship” estimation method for the generalised lambda distribution</i>
----------	---

Description

Estimates parameters of the generalised lambda distribution on the basis of data, using the starship method. The starship method is built on the fact that the generalised lambda distribution ([gld](#)) is a transformation of the uniform distribution. This method finds the parameters that transform the data closest to the uniform distribution. This function uses a grid-based search to find a suitable starting point (using [starship.adaptivegrid](#)) then uses [optim](#) to find the parameters that do this.

Usage

```
starship(data, optim.method = "Nelder-Mead", initgrid = NULL,
inverse.eps = .Machine$double.eps, param="FMKL", optim.control=NULL, return.data=FALSE)
```

Arguments

data	Data to be fitted, as a vector
optim.method	Optimisation method for optim to use, defaults to Nelder-Mead
initgrid	Grid of values of λ_3 and λ_4 to try, in starship.adaptivegrid . This should be a list with elements, <code>lcvect</code> , a vector of values for λ_3 , <code>ldvect</code> , a vector of values for λ_4 and <code>levect</code> , a vector of values for λ_5 (<code>levect</code> is only required if <code>param</code> is <code>fm5</code>). If it is left as <code>NULL</code> , the default grid depends on the parameterisation. For <code>fmk1</code> , both <code>lcvect</code> and <code>ldvect</code> default to:

```
-1.5 -1 -0.5 -0.1 0 0.1 0.2 0.4 0.8 1 1.5
```

(`levect` is `NULL`).

For `rs`, both `lcvect` and `ldvect` default to:

```
0.1 0.2 0.4 0.8 1 1.5
```

(`levect` is `NULL`). Note that this restricts the estimates to only part of the region of the λ_3, λ_4 plane.

For `gpd`, the defaults are: δ :

```
0.3 0.5 0.7
```

and λ :

-1.5 -0.5 0 .2 .4 0.8 1.5 5

For fm5, both lcvect and ldvect default to:

-1.5 -1 -0.5 -0.1 0 0.1 0.2 0.4 0.8 1 1.5

and lcvect defaults to:

-0.5 0.25 0 0.25 0.5

inverse.eps	Accuracy of calculation for the numerical determination of $F(x)$, defaults to <code>.Machine\$double.eps</code>
param	choose parameterisation: <code>fmk1</code> uses <i>Freimer, Mudholkar, Kollia and Lin (1988)</i> (default). <code>rs</code> uses <i>Ramberg and Schmeiser (1974)</i> <code>fm5</code> uses the 5 parameter version of the FMKL parameterisation (paper to appear)
optim.control	List of options for the optimisation step. See <code>optim</code> for details. If left as <code>NULL</code> , the parscale control is set to scale λ_1 and λ_2 by the absolute value of their starting points.
return.data	Logical: Should the function return the data (from the argument data)?

Details

The starship method is described in King & MacGillivray, 1999 (see references). It is built on the fact that the generalised lambda distribution (`gld`) is a transformation of the uniform distribution. Thus the inverse of this transformation is the distribution function for the `gld`. The starship method applies different values of the parameters of the distribution to the distribution function, calculates the depths q corresponding to the data and chooses the parameters that make the depths closest to a uniform distribution.

The closeness to the uniform is assessed by calculating the Anderson-Darling goodness-of-fit test on the transformed data against the uniform, for a sample of size `length(data)`.

This is implemented in 2 stages in this function. First a grid search is carried out, over a small number of possible parameter values (see `starship.adaptivegrid` for details). Then the minimum from this search is given as a starting point for an optimisation of the Anderson-Darling value using `optim`, with method given by `optim.method`

See [GeneralisedLambdaDistribution](#) for details on parameterisations.

Value

`starship` returns an object of class `"starship"`.

`print` prints the estimated values of the parameters, while `summary.starship` prints these by default, but can also provide details of the estimation process (from the components `grid.results` and `optim` detailed below).

An object of class `"starship"` is a list containing at least the following components:

lambda	A vector of length 4 (or 5, for the <i>fm5</i> parameterisation), giving the estimated parameters, in order, λ_1 - location parameter λ_2 - scale parameter λ_3 - first shape parameter λ_4 - second shape parameter (See gld for details of the parameters in the <i>fm5</i> parameterisation) In the <i>gpd</i> parameterisation, the parameters are labelled: α - location parameter β - scale parameter δ - skewness parameter λ - tailweight parameter
grid.results	output from the grid search - see starship.adaptivegrid for details
optim	output from the optim search - optim for details

```

starship.adaptivegrid *Carry out the “starship” estimation method for the generalised lambda distribution using a grid-based search*

Description

Calculates estimates for the generalised lambda distribution on the basis of data, using the starship method. The starship method is built on the fact that the generalised lambda distribution ([gld](#)) is a transformation of the uniform distribution. This method finds the parameters that transform the data closest to the uniform distribution. This function uses a grid-based search.

Usage

```
starship.adaptivegrid(data, initgrid, inverse.eps = 1e-08, param="FMKL")
```

Arguments

data	Data to be fitted, as a vector
initgrid	A list with elements, lcvect, a vector of values for λ_3 , ldvect, a vector of values for λ_4 and levect, a vector of values for λ_5 (levect is only required if param is fm5). The parameter values given in initgrid are not checked with gl.check.lambda .
inverse.eps	Accuracy of calculation for the numerical determination of $F(x)$, defaults to 10^{-8}
param	choose parameterisation: fmk1 uses <i>Freimer, Mudholkar, Kollia and Lin (1988)</i> (default). rs uses <i>Ramberg and Schmeiser (1974)</i> fm5 uses the 5 parameter version of the FMKL parameterisation (paper to appear)

Details

The starship method is described in King & MacGillivray, 1999 (see references). It is built on the fact that the generalised lambda distribution ([gld](#)) is a transformation of the uniform distribution. Thus the inverse of this transformation is the distribution function for the gld. The starship method applies different values of the parameters of the distribution to the distribution function, calculates the depths q corresponding to the data and chooses the parameters that make the depths closest to a uniform distribution.

The closeness to the uniform is assessed by calculating the Anderson-Darling goodness-of-fit test on the transformed data against the uniform, for a sample of size `length(data)`.

This function carries out a grid-based search. This was the original method of King & MacGillivray, 1999, but you are advised to instead use [starship](#) which uses a grid-based search together with an optimisation based search.

See [GeneralisedLambdaDistribution](#) for details on parameterisations.

Value

response	The minimum “response value” — the result of the internal goodness-of-fit measure. This is the return value of <code>starship.obj</code> . See King & MacGillivray, 1999 for more details
lambda	A vector of length 4 giving the values of λ_1 to λ_4 that produce this minimum response, i.e. the estimates

```

starship.obj

Objective function that is minimised in starship estimation method

Description

The starship is a method for fitting the generalised lambda distribution. See [starship](#) for more details.

This function is the objective function minimised in the methods. It is a goodness of fit measure carried out on the depths of the data.

Usage

```
starship.obj(par, data, inverse.eps, param = "fmkl")
```

Arguments

par	parameters of the generalised lambda distribution, a vector of length 4, giving λ_1 to λ_4 . See GeneralisedLambdaDistribution for details on the definitions of these parameters
data	Data — a vector
inverse.eps	Accuracy of calculation for the numerical determination of $F(x)$, defaults to 10^{-8}
param	choose parameterisation: fmkl uses <i>Freimer, Mudholkar, Kollia and Lin (1988)</i> (default). rs uses <i>Ramberg and Schmeiser (1974)</i>

Details

The starship method is described in King & MacGillivray, 1999 (see references). It is built on the fact that the generalised lambda distribution ([gld](#)) is a transformation of the uniform distribution. Thus the inverse of this transformation is the distribution function for the gld. The starship method applies different values of the parameters of the distribution to the distribution function, calculates the depths q corresponding to the data and chooses the parameters that make the depths closest to a uniform distribution.

The closeness to the uniform is assessed by calculating the Anderson-Darling goodness-of-fit test on the transformed data against the uniform, for a sample of size `length(data)`.

This function returns that objective function. It is provided as a separate function to allow users to carry out minimisations using [optim](#) or other methods. The recommended method is to use the [starship](#) function.

Value

The Anderson-Darling goodness of fit measure, computed on the transformed data, compared to a uniform distribution. *Note that this is NOT the goodness-of-fit measure of the generalised lambda distribution with the given parameter values to the data.*
