

# Package ‘forecast’

October 13, 2016

**Version** 7.3

**Title** Forecasting Functions for Time Series and Linear Models

**Description** Methods and tools for displaying and analysing univariate time series forecasts including exponential smoothing via state space models and automatic ARIMA modelling.

**Depends** R (>= 3.0.2), stats, graphics, zoo, timeDate

**Imports** tseries, fracdiff, Rcpp (>= 0.11.0), nnet, colorspace, parallel, ggplot2 (>= 2.0.0)

**Suggests** testthat

**LinkingTo** Rcpp (>= 0.11.0), RcppArmadillo (>= 0.2.35)

**LazyData** yes

**ByteCompile** TRUE

**BugReports** <https://github.com/robjhyndman/forecast/issues>

**License** GPL (>= 2)

**URL** <http://github.com/robjhyndman/forecast>

**NeedsCompilation** yes

**Author** Rob Hyndman [aut, cre, cph]

**Maintainer** Rob Hyndman <Rob.Hyndman@monash.edu>

**Repository** CRAN

**Date/Publication** 2016-10-13 00:38:06

**Index****102**

accuracy

*Accuracy measures for forecast model***Description**

Returns range of summary measures of the forecast accuracy. If `x` is provided, the function measures out-of-sample (test set) forecast accuracy based on `x-f`. If `x` is not provided, the function only produces in-sample (training set) accuracy measures of the forecasts based on `f["x"]-fitted(f)`. All measures are defined and discussed in Hyndman and Koehler (2006).

**Usage**

```
accuracy(f, x, test=NULL, d=NULL, D=NULL)
```

**Arguments**

|      |   |
|------|---|
| f    | An object of class "forecast", or a numerical vector containing forecasts. It will also work with Arima, ets and lm objects if x is omitted – in which case in-sample accuracy measures are returned. |
| x    | An optional numerical vector containing actual values of the same length as object, or a time series overlapping with the times of f.   |
| test | Indicator of which elements of x and f to test. If test is NULL, all elements are used. Otherwise test is a numeric vector containing the indices of the elements to use in the test.                 |
| d    | An integer indicating the number of lag-1 differences to be used for the denominator in MASE calculation. Default value is 1 for non-seasonal series and 0 for seasonal series.                       |
| D    | An integer indicating the number of seasonal differences to be used for the denominator in MASE calculation. Default value is 0 for non-seasonal series and 1 for seasonal series.                    |

**Details**

The measures calculated are:

- ME: Mean Error
- RMSE: Root Mean Squared Error
- MAE: Mean Absolute Error
- MPE: Mean Percentage Error
- MAPE: Mean Absolute Percentage Error
- MASE: Mean Absolute Scaled Error
- ACF1: Autocorrelation of errors at lag 1.

By default, the MASE calculation is scaled using MAE of in-sample naive forecasts for non-seasonal time series, in-sample seasonal naive forecasts for seasonal time series and in-sample mean forecasts for non-time series data.

See Hyndman and Koehler (2006) and Hyndman and Athanasopoulos (2014, Section 2.5) for further details.

**Value**

Matrix giving forecast accuracy measures.

**Author(s)**

Rob J Hyndman

(2014) "Forecasting: principles and practice", OTexts. Section 2.5 "Evaluating forecast accuracy". <http://www.otexts.org/fpp/2/5>.

**Examples**

```

fit1 <- rwf(EuStockMarkets[1:200,1],h=100)
fit2 <- meanf(EuStockMarkets[1:200,1],h=100)
accuracy(fit1)
accuracy(fit2)
accuracy(fit1,EuStockMarkets[201:300,1])
accuracy(fit2,EuStockMarkets[201:300,1])
plot(fit1)
lines(EuStockMarkets[1:300,1])

```

Acf

*(Partial) Autocorrelation and Cross-Correlation Function Estimation***Description**

The function `Acf` computes (and by default plots) an estimate of the autocorrelation function of a (possibly multivariate) time series. Function `Pacf` computes (and by default plots) an estimate of the partial autocorrelation function of a (possibly multivariate) time series. Function `Ccf` computes the cross-correlation or cross-covariance of two univariate series.

**Usage**

```

Acf(x, lag.max = NULL,
    type = c("correlation", "covariance", "partial"),
    plot = TRUE, na.action = na.contiguous, demean=TRUE, ...)
Pacf(x, lag.max=NULL, plot=TRUE, na.action=na.contiguous, ...)
Ccf(x, y, lag.max=NULL, type=c("correlation","covariance"),
    plot=TRUE, na.action=na.contiguous, ...)
taperedacf(x, lag.max=NULL, type=c("correlation", "partial"),
    plot=TRUE, calc.ci=TRUE, level=95, nsim=100, ...)
taperedpacf(x, ...)

```

**Arguments**

|                        |  |
|------------------------|--|
| <code>x</code>         | a univariate or multivariate (not <code>Ccf</code> ) numeric time series object or a numeric vector or matrix.   |
| <code>y</code>         | a univariate numeric time series object or a numeric vector.   |
| <code>lag.max</code>   | maximum lag at which to calculate the acf. Default is $10 \cdot \log_{10}(N/m)$ where $N$ is the number of observations and $m$ the number of series. Will be automatically limited to one less than the number of observations in the series. |
| <code>type</code>      | character string giving the type of acf to be computed. Allowed values are "correlation" (the default), "covariance" or "partial".   |
| <code>plot</code>      | logical. If <code>TRUE</code> (the default) the resulting acf, pacf or ccf is plotted.   |
| <code>na.action</code> | function to handle missing values. Default is <code>na.contiguous</code> . Useful alternatives are <code>na.pass</code> and <code>na.interp</code> .   |

|         |  |
|---------|--|
| demean  | Should covariances be about the sample means?                                |
| calc.ci | If TRUE, confidence intervals for the ACF/PACF estimates are calculated.     |
| level   | Percentage level used for the confidence intervals.                          |
| nsim    | The number of bootstrap samples used in estimating the confidence intervals. |
| ...     | Additional arguments passed to the plotting function.                        |

### Details

The functions improve the [acf](#), [pacf](#) and [ccf](#) functions. The main differences are that `Acf` does not plot a spike at lag 0 when `type=="correlation"` (which is redundant) and the horizontal axes show lags in time units rather than seasonal units.

The tapered versions implement the ACF and PACF estimates and plots described in Hyndman (2015), based on the banded and tapered estimates of autocovariance proposed by McMurry and Politis (2010).

### Value

The `Acf`, `Pacf` and `Ccf` functions return objects of class "acf" as described in [acf](#) from the `stats` package. The `taperedacf` and `taperedpacf` functions return objects of class "mpacf".

taperedpacf(wineind, nsim=50)

## End(Not run)
```

---

arfima *Fit a fractionally differenced ARFIMA model*

---

### Description

An ARFIMA(p,d,q) model is selected and estimated automatically using the Hyndman-Khandakar (2008) algorithm to select p and q and the Haslett and Raftery (1989) algorithm to estimate the parameters including d.

### Usage

```
arfima(y, drange=c(0, 0.5), estim=c("mle","ls"), lambda=NULL, biasadj=FALSE, x=y, ...)
```

### Arguments

|         |  |
|---------|--|
| y       | a univariate time series (numeric vector).   |
| drange  | Allowable values of d to be considered. Default of $c(0, 0.5)$ ensures a stationary model is returned.   |
| estim   | If <code>estim=="ls"</code> , then the ARMA parameters are calculated using the Haslett-Raftery algorithm. If <code>estim=="mle"</code> , then the ARMA parameters are calculated using full MLE via the <a href="#">arima</a> function. |
| lambda  | Box-Cox transformation parameter. Ignored if NULL. Otherwise, data transformed before model is estimated.  |
| biasadj | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities.                            |
| x       | Deprecated. Included for backwards compatibility.  |
| ...     | Other arguments passed to <a href="#">auto.arima</a> when selecting p and q.   |

### Details

This function combines [fracdiff](#) and [auto.arima](#) to automatically select and estimate an ARFIMA model. The fractional differencing parameter is chosen first assuming an ARFIMA(2,d,0) model. Then the data are fractionally differenced using the estimated d and an ARMA model is selected for the resulting time series using [auto.arima](#). Finally, the full ARFIMA(p,d,q) model is re-estimated using [fracdiff](#). If `estim=="mle"`, the ARMA coefficients are refined using [arima](#).

### Value

A list object of S3 class "fracdiff", which is described in the [fracdiff](#) documentation. A few additional objects are added to the list including x (the original time series), and the residuals and fitted values.

```

---

Arima

*Fit ARIMA model to univariate time series*

---

## Description

Largely a wrapper for the [arima](#) function in the stats package. The main difference is that this function allows a drift term. It is also possible to take an ARIMA model from a previous call to Arima and re-apply it to the data y.

## Usage

```
Arima(y, order=c(0,0,0), seasonal=c(0,0,0),
      xreg=NULL, include.mean=TRUE, include.drift=FALSE,
      include.constant, lambda=model$lambda, method=c("CSS-ML", "ML", "CSS"),
      model=NULL, x=y, ...)
```

## Arguments

- |              |  |
|--------------|--|
| y            | a univariate time series of class ts.  |
| order        | A specification of the non-seasonal part of the ARIMA model: the three components (p, d, q) are the AR order, the degree of differencing, and the MA order.  |
| seasonal     | A specification of the seasonal part of the ARIMA model, plus the period (which defaults to frequency(y)). This should be a list with components order and period, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order. |
| xreg         | Optionally, a vector or matrix of external regressors, which must have the same number of rows as y.   |
| include.mean | Should the ARIMA model include a mean term? The default is TRUE for undifferenced series, FALSE for differenced ones (where a mean would not affect the fit nor predictions).  |

|                               |  |
|-------------------------------|--|
| <code>include.drift</code>    | Should the ARIMA model include a linear drift term? (i.e., a linear regression with ARIMA errors is fitted.) The default is FALSE.   |
| <code>include.constant</code> | If TRUE, then <code>include.mean</code> is set to be TRUE for undifferenced series and <code>include.drift</code> is set to be TRUE for differenced series. Note that if there is more than one difference taken, no constant is included regardless of the value of this argument. This is deliberate as otherwise quadratic and higher order polynomial trends would be induced. |
| <code>lambda</code>           | Box-Cox transformation parameter. Ignored if NULL. Otherwise, data transformed before model is estimated.  |
| <code>method</code>           | Fitting method: maximum likelihood or minimize conditional sum-of-squares. The default (unless there are missing values) is to use conditional-sum-of-squares to find starting values, then maximum likelihood.  |
| <code>model</code>            | Output from a previous call to <code>Arima</code> . If <code>model</code> is passed, this same model is fitted to <code>y</code> without re-estimating any parameters.   |
| <code>x</code>                | Deprecated. Included for backwards compatibility.  |
| <code>...</code>              | Additional arguments to be passed to <code>arima</code> .  |

### Details

See the `arima` function in the stats package.

### Value

See the `arima` function in the stats package. The additional objects returned are

|                   |   |
|-------------------|---|
| <code>x</code>    | The time series data                            |
| <code>xreg</code> | The regressors used in fitting (when relevant). |

### Examples

```
fit <- Arima(WWWusage,order=c(3,1,0))
plot(forecast(fit,h=20))

# Fit model to first few years of AirPassengers data
air.model <- Arima(window(AirPassengers,end=1956+11/12),order=c(0,1,1),
                  seasonal=list(order=c(0,1,1),period=12),lambda=0)
plot(forecast(air.model,h=48))
lines(AirPassengers)

# Apply fitted model to later data
```

```
air.model2 <- Arima(window(AirPassengers,start=1957),model=air.model)

# Forecast accuracy measures on the log scale.
# in-sample one-step forecasts.
accuracy(air.model)
# out-of-sample one-step forecasts.
accuracy(air.model2)
# out-of-sample multi-step forecasts
accuracy(forecast(air.model,h=48,lambda=NULL),
         log(window(AirPassengers,start=1957)))
```

---

arima.errors

*ARIMA errors*

---

## Description

Returns original time series after adjusting for regression variables. These are not the same as the residuals. If there are no regression variables in the ARIMA model, then the errors will be identical to the original series. If there are regression variables in the ARIMA model, then the errors will be equal to the original series minus the effect of the regression variables, but leaving in the serial correlation that is modelled with the AR and MA terms. If you want the "residuals", then use `residuals(z)`.

## Usage

```
arima.errors(z)
```

## Arguments

`z` Fitted ARIMA model from [arima](#)

## Value

A time series containing the "errors".

## Author(s)

Rob J Hyndman

## See Also

[arima](#), [residuals](#)

## Examples

```
www.fit <- auto.arima(WWWusage)
www.errors <- arima.errors(www.fit)
par(mfrow=c(2,1))
plot(WWWusage)
plot(www.errors)
```

---

|            |   |
|------------|---|
| arimaorder | <i>Return the order of an ARIMA or ARFIMA model</i> |
|------------|---|

---

**Description**

Returns the order of a univariate ARIMA or ARFIMA model.

**Usage**

```
arimaorder(object)
```

**Arguments**

object            An object of class "Arima", "ar" or "fracdiff". Usually the result of a call to [arima](#), [Arima](#), [auto.arima](#), [ar](#), [arfima](#) or [fracdiff](#).

**Value**

A numerical vector giving the values  $p$ ,  $d$  and  $q$  of the ARIMA or ARFIMA model. For a seasonal ARIMA model, the returned vector contains the values  $p$ ,  $d$ ,  $q$ ,  $P$ ,  $D$ ,  $Q$  and  $m$ , where  $m$  is the period of seasonality.

**Author(s)**

Rob J Hyndman

**See Also**

[ar](#), [auto.arima](#), [Arima](#), [arima](#), [arfima](#).

**Examples**

```
arimaorder(auto.arima(WWWusage))
```

---

|            |   |
|------------|---|
| auto.arima | <i>Fit best ARIMA model to univariate time series</i> |
|------------|---|

---

**Description**

Returns best ARIMA model according to either AIC, AICc or BIC value. The function conducts a search over possible model within the order constraints provided.

**Usage**

```

auto.arima(y, d=NA, D=NA, max.p=5, max.q=5,
           max.P=2, max.Q=2, max.order=5, max.d=2, max.D=1,
           start.p=2, start.q=2, start.P=1, start.Q=1,
           stationary=FALSE, seasonal=TRUE,
           ic=c("aic", "bic"), stepwise=TRUE, trace=FALSE,
           approximation=(length(x)>100 | frequency(x)>12),
           truncate=NULL, xreg=NULL,
           test=c("kpss", "adf", "pp"), seasonal.test=c("ocsb", "ch"),
           allowdrift=TRUE, allowmean=TRUE, lambda=NULL, biasadj=FALSE,
           parallel=FALSE, num.cores=2, x=y, ...)

```

**Arguments**

|               |   |
|---------------|---|
| y             | a univariate time series  |
| d             | Order of first-differencing. If missing, will choose a value based on KPSS test.  |
| D             | Order of seasonal-differencing. If missing, will choose a value based on OCSB test.   |
| max.p         | Maximum value of p  |
| max.q         | Maximum value of q  |
| max.P         | Maximum value of P  |
| max.Q         | Maximum value of Q  |
| max.order     | Maximum value of p+q+P+Q if model selection is not stepwise.  |
| max.d         | Maximum number of non-seasonal differences  |
| max.D         | Maximum number of seasonal differences  |
| start.p       | Starting value of p in stepwise procedure.  |
| start.q       | Starting value of q in stepwise procedure.  |
| start.P       | Starting value of P in stepwise procedure.  |
| start.Q       | Starting value of Q in stepwise procedure.  |
| stationary    | If TRUE, restricts search to stationary models.   |
| seasonal      | If FALSE, restricts search to non-seasonal models.  |
| ic            | Information criterion to be used in model selection.  |
| stepwise      | If TRUE, will do stepwise selection (faster). Otherwise, it searches over all models. Non-stepwise selection can be very slow, especially for seasonal models.  |
| trace         | If TRUE, the list of ARIMA models considered will be reported.  |
| approximation | If TRUE, estimation is via conditional sums of squares and the information criteria used for model selection are approximated. The final model is still computed using maximum likelihood estimation. Approximation should be used for long time series or a high seasonal period to avoid excessive computation times. |
| truncate      | An integer value indicating how many observations to use in model selection. The last truncate values of the series are used to select a model when truncate is not NULL and approximation=TRUE. All observations are used if either truncate=NULL or approximation=FALSE.  |

|               |  |
|---------------|--|
| xreg          | Optionally, a vector or matrix of external regressors, which must have the same number of rows as y.   |
| test          | Type of unit root test to use. See <a href="#">ndiffs</a> for details.   |
| seasonal.test | This determines which seasonal unit root test is used. See <a href="#">nsdiffs</a> for details.  |
| allowdrift    | If TRUE, models with drift terms are considered.   |
| allowmean     | If TRUE, models with a non-zero mean are considered.   |
| lambda        | Box-Cox transformation parameter. Ignored if NULL. Otherwise, data transformed before model is estimated.  |
| biasadj       | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities.                                    |
| parallel      | If TRUE and <code>stepwise = FALSE</code> , then the specification search is done in parallel. This can give a significant speedup on multicore machines.  |
| num.cores     | Allows the user to specify the amount of parallel processes to be used if <code>parallel = TRUE</code> and <code>stepwise = FALSE</code> . If NULL, then the number of logical cores is automatically detected and all available cores are used. |
| x             | Deprecated. Included for backwards compatibility.  |
| ...           | Additional arguments to be passed to <a href="#">arima</a> .   |

### Details

Non-stepwise selection can be slow, especially for seasonal data. Stepwise algorithm outlined in Hyndman and Khandakar (2008) except that the default method for selecting seasonal differences is now the OCSB test rather than the Canova-Hansen test.

### Value

Same as for [Arima](#)

### Author(s)

Rob J Hyndman

### References

Hyndman, R.J. and Khandakar, Y. (2008) "Automatic time series forecasting: The forecast package for R", *Journal of Statistical Software*, **26**(3).

### See Also

### Examples

```
fit <- auto.arima(WWWusage)
plot(forecast(fit,h=20))
```

---

autoplot.acf                      *ggplot (Partial) Autocorrelation and Cross-Correlation Function Estimation*

---

## Description

Produces a ggplot object of their equivalent Acf, Pacf, Ccf, taperedacf and taperedpacf functions. If autoplot is given an acf or mpacf function, then an appropriate ggplot object will be created.

## Usage

```
## S3 method for class 'acf'
autoplot(object, ci=0.95, ...)
## S3 method for class 'mpacf'
autoplot(object, ...)

ggAcf(x, lag.max = NULL,
      type = c("correlation", "covariance", "partial"),
      plot = TRUE, na.action = na.contiguous, demean=TRUE, ...)
ggPacf(x, ...)
ggCcf(x, y, lag.max=NULL, type=c("correlation","covariance"),
      plot=TRUE, na.action=na.contiguous, ...)
ggtaperedacf(x, lag.max=NULL, type=c("correlation", "partial"),
             plot=TRUE, calc.ci=TRUE, level=95, nsim=100, ...)
ggtaperedpacf(x, ...)
```

## Arguments

|           |   |
|-----------|---|
| object    | Object of class "acf".  |
| x         | a univariate or multivariate (not Ccf) numeric time series object or a numeric vector or matrix.  |
| y         | a univariate numeric time series object or a numeric vector.  |
| ci        | coverage probability for confidence interval. Plotting of the confidence interval is suppressed if ci is zero or negative.                                    |
| lag.max   | maximum lag at which to calculate the acf.  |
| type      | character string giving the type of acf to be computed. Allowed values are "correlation" (the default), "covariance" or "partial".                            |
| plot      | logical. If TRUE (the default) the resulting acf, pacf or ccf is plotted.   |
| na.action | function to handle missing values. Default is <a href="#">na.contiguous</a> . Useful alternatives are <a href="#">na.pass</a> and <a href="#">na.interp</a> . |
| demean    | Should covariances be about the sample means?   |
| calc.ci   | If TRUE, confidence intervals for the ACF/PACF estimates are calculated.  |
| level     | Percentage level used for the confidence intervals.   |
| nsim      | The number of bootstrap samples used in estimating the confidence intervals.  |
| ...       | Other plotting parameters to affect the plot.   |

**Value**

None. Function produces a ggplot graph.

ggtaperedacf(wineind)
ggtaperedpacf(wineind)
## End(Not run)
ggCcfc(mdeaths, fdeaths)
```

---

autoplot.decomposed.ts

*ggplot of a decomposed time series object*

---

**Description**

Produces a ggplot object of decomposed components of a time series object

**Usage**

```
## S3 method for class 'decomposed.ts'
autoplot(object, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | Object of class “decomposed.ts” to be plotted. |
| ...    | Other plotting parameters to affect the plot.  |

**Value**

None. Function produces a ggplot graph.

autoplot.ts                      *Automatically create a ggplot for time series objects*

---

## Description

autoplot takes an object of type ts or mts and creates a ggplot object suitable for usage with stat\_forecast.

fortify.ts takes a ts object and converts it into a data frame (for usage with ggplot2).

## Usage

```
## S3 method for class 'ts'  
autoplot(object, ...)  
## S3 method for class 'mts'  
autoplot(object, facets=FALSE, ...)  
## S3 method for class 'ts'  
fortify(model,data, ...)
```

## Arguments

|        |   |
|--------|---|
| object | Object of class “ts” or “mts”.  |
| facets | If TRUE, multiple time series will be faceted. If FALSE, each series will be assigned a colour. |
| model  | Object of class “ts” to be converted to “data.frame”.   |
| data   | Not used (required for <a href="#">fortify</a> method)  |
| ...    | Other plotting parameters to affect the plot.   |

## Value

None. Function produces a ggplot graph.

autoplot(lungDeaths, facets=TRUE)
```

---

|      |   |
|------|---|
| bats | <i>BATS model (Exponential smoothing state space model with Box-Cox transformation, ARMA errors, Trend and Seasonal components)</i> |
|------|---|

---

### Description

Fits a BATS model applied to  $y$ , as described in De Livera, Hyndman & Snyder (2011). Parallel processing is used by default to speed up the computations.

### Usage

```
bats(y, use.box.cox=NULL, use.trend=NULL, use.damped.trend=NULL,
     seasonal.periods=NULL, use.arma.errors=TRUE, use.parallel=length(y)>1000,
     num.cores=2, bc.lower=0, bc.upper=1, model=NULL, ...)
```

### Arguments

|                               |   |
|-------------------------------|---|
| <code>y</code>                | The time series to be forecast. Can be numeric, msts or ts. Only univariate time series are supported.  |
| <code>use.box.cox</code>      | TRUE/FALSE indicates whether to use the Box-Cox transformation or not. If NULL then both are tried and the best fit is selected by AIC.   |
| <code>use.trend</code>        | TRUE/FALSE indicates whether to include a trend or not. If NULL then both are tried and the best fit is selected by AIC.  |
| <code>use.damped.trend</code> | TRUE/FALSE indicates whether to include a damping parameter in the trend or not. If NULL then both are tried and the best fit is selected by AIC.   |
| <code>seasonal.periods</code> | If $y$ is a numeric then seasonal periods can be specified with this parameter.   |
| <code>use.arma.errors</code>  | TRUE/FALSE indicates whether to include ARMA errors or not. If TRUE the best fit is selected by AIC. If FALSE then the selection algorithm does not consider ARMA errors.   |
| <code>use.parallel</code>     | TRUE/FALSE indicates whether or not to use parallel processing.   |
| <code>num.cores</code>        | The number of parallel processes to be used if using parallel processing. If NULL then the number of logical cores is detected and all available cores are used.  |
| <code>bc.lower</code>         | The lower limit (inclusive) for the Box-Cox transformation.   |
| <code>bc.upper</code>         | The upper limit (inclusive) for the Box-Cox transformation.   |
| <code>model</code>            | Output from a previous call to <code>bats</code> . If <code>model</code> is passed, this same model is fitted to $y$ without re-estimating any parameters.  |
| <code>...</code>              | Additional arguments to be passed to <code>auto.arima</code> when choose an ARMA( $p$ , $q$ ) model for the errors. (Note that <code>xreg</code> will be ignored, as will any arguments concerning seasonality and differencing, but arguments controlling the values of $p$ and $q$ will be used.) |

**Value**

An object of class "bats". The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `bats` and associated functions. The fitted model is designated BATS( $\omega$ ,  $p, q$ ,  $\phi$ ,  $m_1, \dots, m_J$ ) where  $\omega$  is the Box-Cox parameter and  $\phi$  is the damping parameter; the error is modelled as an ARMA( $p, q$ ) process and  $m_1, \dots, m_J$  list the seasonal periods used in the model.

**Examples**

```
## Not run:
fit <- bats(USAccDeaths)
plot(forecast(fit))

taylor.fit <- bats(taylor)
plot(forecast(taylor.fit))
## End(Not run)
```

---

|         |  |
|---------|--|
| bizdays | <i>Number of trading days in each season</i> |
|---------|--|

---

**Description**

Returns number of trading days in each month or quarter of the observed time period in a major financial center.

**Usage**

```
bizdays(x, FinCenter = c("New York", "London", "NERC", "Tokyo", "Zurich"))
```

**Arguments**

|                        |                                  |
|------------------------|----------------------------------|
| <code>x</code>         | Monthly or quarterly time series |
| <code>FinCenter</code> | Major financial center.          |

**Details**

Useful for trading days length adjustments. More on how to define "business days", please refer to [isBizday](#).

**Value**

Time series

x <- ts(rnorm(30), start = c(2013, 2), frequency = 12)
bizdays(x, FinCenter = "New York")
```

---

BoxCox

*Box Cox Transformation*

---

**Description**

BoxCox() returns a transformation of the input variable using a Box-Cox transformation. InvBoxCox() reverses the transformation.

**Usage**

```
BoxCox(x, lambda)
InvBoxCox(x, lambda)
```

**Arguments**

x                    a numeric vector or time series  
lambda                transformation parameter

**Details**

The Box-Cox transformation is given by

$$f_{\lambda}(x) = \frac{x^{\lambda} - 1}{\lambda}$$

if  $\lambda \neq 0$ . For  $\lambda = 0$ ,

$$f_0(x) = \log(x)$$

**Value**

a numeric vector of the same length as x.

**Author(s)**

Rob J Hyndman

lynx.fit <- ar(BoxCox(lynx, lambda))
plot(forecast(lynx.fit, h=20, lambda=lambda))
```

---

BoxCox.lambda

*Automatic selection of Box-Cox transformation parameter*

---

**Description**

If `method=="guerrero"`, Guerrero's (1993) method is used, where `lambda` minimizes the coefficient of variation for subseries of `x`.

If `method=="loglik"`, the value of `lambda` is chosen to maximize the profile log likelihood of a linear model fitted to `x`. For non-seasonal data, a linear time trend is fitted while for seasonal data, a linear time trend with seasonal dummy variables is used.

**Usage**

```
BoxCox.lambda(x, method=c("guerrero", "loglik"), lower=-1, upper=2)
```

**Arguments**

|                     |   |
|---------------------|---|
| <code>x</code>      | a numeric vector or time series                               |
| <code>method</code> | Choose method to be used in calculating <code>lambda</code> . |
| <code>lower</code>  | Lower limit for possible <code>lambda</code> values.          |
| <code>upper</code>  | Upper limit for possible <code>lambda</code> values.          |

**Value**

a number indicating the Box-Cox transformation parameter.

**Author(s)**

Leanne Chhay and Rob J Hyndman

plot(forecast(air.fit))
```

---

croston

*Forecasts for intermittent demand using Croston's method*

---

## Description

Returns forecasts and other information for Croston's forecasts applied to  $y$ .

## Usage

```
croston(y, h=10, alpha=0.1, x=y)
```

## Arguments

|          |   |
|----------|---|
| $y$      | a numeric vector or time series                   |
| $h$      | Number of periods for forecasting.                |
| $\alpha$ | Value of alpha. Default value is 0.1.             |
| $x$      | Deprecated. Included for backwards compatibility. |

## Details

Based on Croston's (1972) method for intermittent demand forecasting, also described in Shenstone and Hyndman (2005). Croston's method involves using simple exponential smoothing (SES) on the non-zero elements of the time series and a separate application of SES to the times between non-zero elements of the time series. The smoothing parameters of the two applications of SES are assumed to be equal and are denoted by  $\alpha$ .

Note that prediction intervals are not computed as Croston's method has no underlying stochastic model. The separate forecasts for the non-zero demands, and for the times between non-zero demands do have prediction intervals based on ETS(A,N,N) models.

**Value**

An object of class "forecast" is a list containing at least the following elements:

|           |   |
|-----------|---|
| model     | A list containing information about the fitted model. The first element gives the model used for non-zero demands. The second element gives the model used for times between non-zero demands. Both elements are of class forecast. |
| method    | The name of the forecasting method as a character string  |
| mean      | Point forecasts as a time series  |
| x         | The original time series (either object itself or the time series used to create the model stored as object).   |
| residuals | Residuals from the fitted model. That is y minus fitted values.   |
| fitted    | Fitted values (one-step forecasts)  |

The function summary is used to obtain and print a summary of the results, while the function plot produces a plot of the forecasts.

The generic accessor functions fitted.values and residuals extract useful features of the value returned by croston and associated functions.

fit2 <- tslm(y ~ season)
CV(fit1)
CV(fit2)
```

---

dm.test *Diebold-Mariano test for predictive accuracy*

---

**Description**

The Diebold-Mariano test compares the forecast accuracy of two forecast methods.

**Usage**

```
dm.test(e1, e2, alternative=c("two.sided", "less", "greater"),
        h=1, power=2)
```

**Arguments**

|             |   |
|-------------|---|
| e1          | Forecast errors from method 1.  |
| e2          | Forecast errors from method 2.  |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. |
| h           | The forecast horizon used in calculating e1 and e2.   |
| power       | The power used in the loss function. Usually 1 or 2.  |

**Details**

This function implements the modified test proposed by Harvey, Leybourne and Newbold (1997). The null hypothesis is that the two methods have the same forecast accuracy. For `alternative="less"`, the alternative hypothesis is that method 2 is less accurate than method 1. For `alternative="greater"`, the alternative hypothesis is that method 2 is more accurate than method 1. For `alternative="two.sided"`, the alternative hypothesis is that method 1 and method 2 have different levels of accuracy.

**Value**

A list with class "hctest" containing the following components:

|             |  |
|-------------|--|
| statistic   | the value of the DM-statistic.                                 |
| parameter   | the forecast horizon and loss function power used in the test. |
| alternative | a character string describing the alternative hypothesis.      |
| p.value     | the p-value for the test.                                      |
| method      | a character string with the value "Diebold-Mariano Test".      |
| data.name   | a character vector giving the names of the two error series.   |

accuracy(f2.out)
dm.test(residuals(f1.out),residuals(f2.out),h=1)
```

---

dshw

*Double-Seasonal Holt-Winters Forecasting*

---

### Description

Returns forecasts using Taylor's (2003) Double-Seasonal Holt-Winters method.

### Usage

```
dshw(y, period1, period2, h=2*max(period1,period2),
     alpha=NULL, beta=NULL, gamma=NULL, omega=NULL, phi=NULL,
     lambda=NULL, biasadj=FALSE, armethod=TRUE, model = NULL)
```

### Arguments

|          |   |
|----------|---|
| y        | Either an <code>msts</code> object with two seasonal periods or a numeric vector.   |
| period1  | Period of the shorter seasonal period. Only used if y is not an <code>msts</code> object.   |
| period2  | Period of the longer seasonal period. Only used if y is not an <code>msts</code> object.  |
| h        | Number of periods for forecasting.  |
| alpha    | Smoothing parameter for the level. If NULL, the parameter is estimated using least squares.   |
| beta     | Smoothing parameter for the slope. If NULL, the parameter is estimated using least squares.   |
| gamma    | Smoothing parameter for the first seasonal period. If NULL, the parameter is estimated using least squares.   |
| omega    | Smoothing parameter for the second seasonal period. If NULL, the parameter is estimated using least squares.  |
| phi      | Autoregressive parameter. If NULL, the parameter is estimated using least squares.  |
| lambda   | Box-Cox transformation parameter. Ignored if NULL. Otherwise, data transformed before model is estimated.   |
| biasadj  | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities. |
| armethod | If TRUE, the forecasts are adjusted using an AR(1) model for the errors.  |
| model    | If it's specified, an existing model is applied to a new data set.  |

## Details

Taylor's (2003) double-seasonal Holt-Winters method uses additive trend and multiplicative seasonality, where there are two seasonal components which are multiplied together. For example, with a series of half-hourly data, one would set `period1=48` for the daily period and `period2=336` for the weekly period. The smoothing parameter notation used here is different from that in Taylor (2003); instead it matches that used in Hyndman et al (2008) and that used for the `ets` function.

## Value

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `dshw`.

An object of class "forecast" is a list containing at least the following elements:

|                        |   |
|------------------------|---|
| <code>model</code>     | A list containing information about the fitted model  |
| <code>method</code>    | The name of the forecasting method as a character string  |
| <code>mean</code>      | Point forecasts as a time series  |
| <code>x</code>         | The original time series (either object itself or the time series used to create the model stored as object). |
| <code>residuals</code> | Residuals from the fitted model. That is <code>x</code> minus fitted values.                                  |
| <code>fitted</code>    | Fitted values (one-step forecasts)  |

```

---

easter

*Easter holidays in each season*

---

### Description

Returns a vector of 0's and 1's or fractional results if Easter spans March and April in the observed time period. Easter is defined as the days from Good Friday to Easter Sunday inclusively, plus optionally Easter Monday if `easter.mon=TRUE`.

### Usage

```
easter(x, easter.mon = FALSE)
```

### Arguments

|            |  |
|------------|--|
| x          | Monthly or quarterly time series                               |
| easter.mon | If TRUE, the length of Easter holidays includes Easter Monday. |

### Details

Useful for adjusting calendar effects.

### Value

Time series

### Author(s)

Earo Wang

### Examples

```
easter(wineind, easter.mon = TRUE)
```

---

ets *Exponential smoothing state space model*

---

**Description**

Returns ets model applied to y.

**Usage**

```
ets(y, model="ZZZ", damped=NULL, alpha=NULL, beta=NULL, gamma=NULL,
    phi=NULL, additive.only=FALSE, lambda=NULL, biasadj=FALSE,
    lower=c(rep(0.0001,3), 0.8), upper=c(rep(0.9999,3),0.98),
    opt.crit=c("lik","amse","mse","sigma","mae"), nmse=3,
    bounds=c("both","usual","admissible"), ic=c("aicc","aic","bic"),
    restrict=TRUE, allow.multiplicative.trend=FALSE, use.initial.values=FALSE, ...)
```

**Arguments**

|               |  |
|---------------|--|
| y             | a numeric vector or time series  |
| model         | Usually a three-character string identifying method using the framework terminology of Hyndman et al. (2002) and Hyndman et al. (2008). The first letter denotes the error type ("A", "M" or "Z"); the second letter denotes the trend type ("N","A","M" or "Z"); and the third letter denotes the season type ("N","A","M" or "Z"). In all cases, "N"=none, "A"=additive, "M"=multiplicative and "Z"=automatically selected. So, for example, "ANN" is simple exponential smoothing with additive errors, "MAM" is multiplicative Holt-Winters' method with multiplicative errors, and so on.<br><br>It is also possible for the model to be of class "ets", and equal to the output from a previous call to ets. In this case, the same model is fitted to y without re-estimating any smoothing parameters. See also the use.initial.values argument. |
| damped        | If TRUE, use a damped trend (either additive or multiplicative). If NULL, both damped and non-damped trends will be tried and the best model (according to the information criterion ic) returned.   |
| alpha         | Value of alpha. If NULL, it is estimated.  |
| beta          | Value of beta. If NULL, it is estimated.   |
| gamma         | Value of gamma. If NULL, it is estimated.  |
| phi           | Value of phi. If NULL, it is estimated.  |
| additive.only | If TRUE, will only consider additive models. Default is FALSE.   |
| lambda        | Box-Cox transformation parameter. Ignored if NULL. Otherwise, data transformed before model is estimated. When lambda is specified, additive.only is set to TRUE.  |
| biasadj       | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities.  |

|                            |   |
|----------------------------|---|
| lower                      | Lower bounds for the parameters (alpha, beta, gamma, phi)   |
| upper                      | Upper bounds for the parameters (alpha, beta, gamma, phi)   |
| opt.crit                   | Optimization criterion. One of "mse" (Mean Square Error), "amse" (Average MSE over first nmse forecast horizons), "sigma" (Standard deviation of residuals), "mae" (Mean of absolute residuals), or "lik" (Log-likelihood, the default).              |
| nmse                       | Number of steps for average multistep MSE ( $1 \leq \text{nmse} \leq 30$ ).   |
| bounds                     | Type of parameter space to impose: "usual" indicates all parameters must lie between specified lower and upper bounds; "admissible" indicates parameters must lie in the admissible space; "both" (default) takes the intersection of these regions.  |
| ic                         | Information criterion to be used in model selection.  |
| restrict                   | If TRUE (default), the models with infinite variance will not be allowed.   |
| allow.multiplicative.trend | If TRUE, models with multiplicative trend are allowed when searching for a model. Otherwise, the model space excludes them. This argument is ignored if a multiplicative trend model is explicitly requested (e.g., using <code>model="MMN"</code> ). |
| use.initial.values         | If TRUE and model is of class "ets", then the initial values in the model are also not re-estimated.  |
| ...                        | Other undocumented arguments.   |

## Details

Based on the classification of methods as described in Hyndman et al (2008).

The methodology is fully automatic. The only required argument for ets is the time series. The model is chosen automatically if not specified. This methodology performed extremely well on the M3-competition data. (See Hyndman, et al, 2002, below.)

## Value

An object of class "ets".

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by ets and associated functions.

```

---

|               |   |
|---------------|---|
| findfrequency | <i>Find dominant frequency of a time series</i> |
|---------------|---|

---

### Description

findfrequency returns the period of the dominant frequency of a time series. For seasonal data, it will return the seasonal period. For cyclic data, it will return the average cycle length.

### Usage

```
findfrequency(x)
```

### Arguments

x                    a numeric vector or time series

### Details

The dominant frequency is determined from a spectral analysis of the time series. First, a linear trend is removed, then the spectral density function is estimated from the best fitting autoregressive model (based on the AIC). If there is a large (possibly local) maximum in the spectral density function at frequency  $f$ , then the function will return the period  $1/f$  (rounded to the nearest integer). If no such dominant frequency can be found, the function will return 1.

### Value

an integer value

### Author(s)

Rob J Hyndman

### Examples

```
findfrequency(USAccDeaths) # Monthly data
findfrequency(taylor) # Half-hourly data
findfrequency(lynx) # Annual data
```

---

|          |                                |
|----------|--------------------------------|
| forecast | <i>Forecasting time series</i> |
|----------|--------------------------------|

---

### Description

forecast is a generic function for forecasting from time series or time series models. The function invokes particular *methods* which depend on the class of the first argument.

For example, the function `forecast.Arima` makes forecasts based on the results produced by `arima`.

The function `forecast.ts` makes forecasts using `ets` models (if the data are non-seasonal or the seasonal period is 12 or less) or `stlf` (if the seasonal period is 13 or more).

### Usage

```
forecast(object,...)
## S3 method for class 'ts'
forecast(object, h = ifelse(frequency(object) > 1, 2 * frequency(object), 10) ,
         level=c(80,95), fan=FALSE, robust=FALSE, lambda=NULL, find.frequency=FALSE,
         allow.multiplicative.trend=FALSE, ...)
```

### Arguments

|                            |   |
|----------------------------|---|
| object                     | a time series or time series model for which forecasts are required   |
| h                          | Number of periods for forecasting   |
| level                      | Confidence level for prediction intervals.  |
| fan                        | If TRUE, level is set to seq(51, 99, by=3). This is suitable for fan plots.   |
| robust                     | If TRUE, the function is robust to missing values and outliers in object. This argument is only valid when object is of class ts.   |
| lambda                     | Box-Cox transformation parameter.   |
| find.frequency             | If TRUE, the function determines the appropriate period, if the data is of unknown period.  |
| allow.multiplicative.trend | If TRUE, then ETS models with multiplicative trends are allowed. Otherwise, only additive or no trend ETS models are permitted.   |
| ...                        | Additional arguments affecting the forecasts produced. <code>forecast.ts</code> passes these to <code>forecast.ets</code> or <code>stlf</code> depending on the frequency of the time series. |

### Value

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessors functions `fitted.values` and `residuals` extract various useful features of the value returned by `forecast$model`.

An object of class "forecast" is a list usually containing at least the following elements:

|           |  |
|-----------|--|
| model     | A list containing information about the fitted model   |
| method    | The name of the forecasting method as a character string   |
| mean      | Point forecasts as a time series   |
| lower     | Lower limits for prediction intervals  |
| upper     | Upper limits for prediction intervals  |
| level     | The confidence values associated with the prediction intervals   |
| x         | The original time series (either object itself or the time series used to create the model stored as object).      |
| residuals | Residuals from the fitted model. For models with additive errors, the residuals will be x minus the fitted values. |
| fitted    | Fitted values (one-step forecasts)   |

**Author(s)**

Rob J Hyndman

---

forecast.Arima      *Forecasting using ARIMA or ARFIMA models*

---

**Description**

Returns forecasts and other information for univariate ARIMA models.

**Usage**

```
## S3 method for class 'Arima'
forecast(object, h=ifelse(object$arma[5]>1,2*object$arma[5],10),
  level=c(80,95), fan=FALSE, xreg=NULL, lambda=object$lambda,
  bootstrap=FALSE, npaths=5000, biasadj=FALSE, ...)
## S3 method for class 'ar'
forecast(object, h=10, level=c(80,95), fan=FALSE, lambda=NULL,
  bootstrap=FALSE, npaths=5000, biasadj=FALSE, ...)
## S3 method for class 'fracdiff'
forecast(object, h=10, level=c(80,95), fan=FALSE,
  lambda=object$lambda, biasadj=FALSE, ...)
```

**Arguments**

|           |  |
|-----------|--|
| object    | An object of class "Arima", "ar" or "fracdiff". Usually the result of a call to <a href="#">arima</a> , <a href="#">auto.arima</a> , <a href="#">ar</a> , <a href="#">arfima</a> or <a href="#">fracdiff</a> . |
| h         | Number of periods for forecasting. If <code>xreg</code> is used, <code>h</code> is ignored and the number of forecast periods is set to the number of rows of <code>xreg</code> .                              |
| level     | Confidence level for prediction intervals.   |
| fan       | If TRUE, level is set to <code>seq(51, 99, by=3)</code> . This is suitable for fan plots.  |
| xreg      | Future values of an regression variables (for class <code>Arima</code> objects only).  |
| lambda    | Box-Cox transformation parameter. Ignored if NULL. Otherwise, forecasts back-transformed via an inverse Box-Cox transformation.  |
| biasadj   | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities.  |
| bootstrap | If TRUE, then prediction intervals computed using simulation with resampled errors.  |
| npaths    | Number of sample paths used in computing simulated prediction intervals when <code>bootstrap=TRUE</code> .   |
| ...       | Other arguments.   |

**Details**

For `Arima` or `ar` objects, the function calls [predict.Arima](#) or [predict.ar](#) and constructs an object of class "forecast" from the results. For `fracdiff` objects, the calculations are all done within [forecast.fracdiff](#) using the equations given by Peiris and Perera (1988).

**Value**

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `forecast.Arima`.

An object of class "forecast" is a list containing at least the following elements:

|           |   |
|-----------|---|
| model     | A list containing information about the fitted model  |
| method    | The name of the forecasting method as a character string  |
| mean      | Point forecasts as a time series  |
| lower     | Lower limits for prediction intervals   |
| upper     | Upper limits for prediction intervals   |
| level     | The confidence values associated with the prediction intervals  |
| x         | The original time series (either object itself or the time series used to create the model stored as object). |
| residuals | Residuals from the fitted model. That is <code>x</code> minus fitted values.                                  |
| fitted    | Fitted values (one-step forecasts)  |

fit <- arfima(x)
plot(forecast(fit,h=30))
```

---

forecast.bats

*Forecasting using BATS and TBATS models*

---

**Description**

Forecasts h steps ahead with a BATS model. Prediction intervals are also produced.

**Usage**

```
## S3 method for class 'bats'
forecast(object, h, level=c(80,95), fan=FALSE, biasadj=FALSE, ...)
## S3 method for class 'tbats'
forecast(object, h, level=c(80,95), fan=FALSE, biasadj=FALSE, ...)
```

**Arguments**

|         |   |
|---------|---|
| object  | An object of class "bats". Usually the result of a call to <a href="#">bats</a> .   |
| h       | Number of periods for forecasting. Default value is twice the largest seasonal period (for seasonal data) or ten (for non-seasonal data).   |
| level   | Confidence level for prediction intervals.  |
| fan     | If TRUE, level is set to seq(51, 99, by=3). This is suitable for fan plots.   |
| biasadj | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities. |
| ...     | Other arguments, currently ignored.   |

**Value**

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `forecast.bats`.

An object of class "forecast" is a list containing at least the following elements:

|                        |   |
|------------------------|---|
| <code>model</code>     | A copy of the bats object   |
| <code>method</code>    | The name of the forecasting method as a character string  |
| <code>mean</code>      | Point forecasts as a time series  |
| <code>lower</code>     | Lower limits for prediction intervals   |
| <code>upper</code>     | Upper limits for prediction intervals   |
| <code>level</code>     | The confidence values associated with the prediction intervals  |
| <code>x</code>         | The original time series (either object itself or the time series used to create the model stored as object). |
| <code>residuals</code> | Residuals from the fitted model.  |
| <code>fitted</code>    | Fitted values (one-step forecasts)  |

forecast.ets

*Forecasting using ETS models***Description**

Returns forecasts and other information for univariate ETS models.

**Usage**

```
## S3 method for class 'ets'
forecast(object, h=ifelse(object$m>1, 2*object$m, 10),
         level=c(80,95), fan=FALSE, simulate=FALSE, bootstrap=FALSE,
         npaths=5000, PI=TRUE, lambda=object$lambda, biasadj=FALSE, ...)
```

**Arguments**

|           |   |
|-----------|---|
| object    | An object of class "ets". Usually the result of a call to <code>ets</code> .  |
| h         | Number of periods for forecasting   |
| level     | Confidence level for prediction intervals.  |
| fan       | If TRUE, level is set to <code>seq(51,99,by=3)</code> . This is suitable for fan plots.   |
| simulate  | If TRUE, prediction intervals produced by simulation rather than using analytic formulae.   |
| bootstrap | If TRUE, and if <code>simulate=TRUE</code> , then simulation uses resampled errors rather than normally distributed errors.   |
| npaths    | Number of sample paths used in computing simulated prediction intervals.  |
| PI        | If TRUE, prediction intervals are produced, otherwise only point forecasts are calculated. If PI is FALSE, then <code>level</code> , <code>fan</code> , <code>simulate</code> , <code>bootstrap</code> and <code>npaths</code> are all ignored. |
| lambda    | Box-Cox transformation parameter. Ignored if NULL. Otherwise, forecasts back-transformed via an inverse Box-Cox transformation.   |
| biasadj   | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities.                                   |
| ...       | Other arguments.  |

**Value**

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `forecast.ets`.

An object of class "forecast" is a list containing at least the following elements:

|           |   |
|-----------|---|
| model     | A list containing information about the fitted model  |
| method    | The name of the forecasting method as a character string  |
| mean      | Point forecasts as a time series  |
| lower     | Lower limits for prediction intervals   |
| upper     | Upper limits for prediction intervals   |
| level     | The confidence values associated with the prediction intervals  |
| x         | The original time series (either object itself or the time series used to create the model stored as object).   |
| residuals | Residuals from the fitted model. For models with additive errors, the residuals are $x - \text{fitted values}$ . For models with multiplicative errors, the residuals are equal to $x / (\text{fitted values}) - 1$ . |
| fitted    | Fitted values (one-step forecasts)  |

**Author(s)**

Rob J Hyndman

**Examples**

```
fit <- ets(USAccDeaths)
plot(forecast(fit,h=48))
```

---

forecast.HoltWinters    *Forecasting using Holt-Winters objects*

---

**Description**

Returns forecasts and other information for univariate Holt-Winters time series models.

**Usage**

```
## S3 method for class 'HoltWinters'
forecast(object, h=ifelse(frequency(object$x)>1,2*frequency(object$x),10),
         level=c(80,95),fan=FALSE,lambda=NULL, biasadj=FALSE,...)
```

**Arguments**

|         |   |
|---------|---|
| object  | An object of class "HoltWinters". Usually the result of a call to <code>HoltWinters</code> .  |
| h       | Number of periods for forecasting   |
| level   | Confidence level for prediction intervals.  |
| fan     | If TRUE, level is set to <code>seq(51,99,by=3)</code> . This is suitable for fan plots.   |
| lambda  | Box-Cox transformation parameter. Ignored if NULL. Otherwise, forecasts back-transformed via an inverse Box-Cox transformation.   |
| biasadj | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities. |
| ...     | Other arguments.  |

**Details**

This function calls `predict.HoltWinters` and constructs an object of class "forecast" from the results.

It is included for completeness, but the `ets` is recommended for use instead of `HoltWinters`.

**Value**

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `forecast.HoltWinters`.

An object of class "forecast" is a list containing at least the following elements:

|           |   |
|-----------|---|
| model     | A list containing information about the fitted model  |
| method    | The name of the forecasting method as a character string  |
| mean      | Point forecasts as a time series  |

forecast.lm

*Forecast a linear model with possible time series components*

---

**Description**

forecast.lm is used to predict linear models, especially those involving trend and seasonality components.

**Usage**

```
## S3 method for class 'lm'
forecast(object, newdata, h=10, level=c(80,95), fan=FALSE,
         lambda=object$lambda, biasadj=FALSE, ts=TRUE, ...)
```

**Arguments**

|         |  |
|---------|--|
| object  | Object of class "lm", usually the result of a call to <a href="#">lm</a> or <a href="#">tslm</a> .   |
| newdata | An optional data frame in which to look for variables with which to predict. If omitted, it is assumed that the only variables are trend and season, and h forecasts are produced.   |
| level   | Confidence level for prediction intervals.   |
| fan     | If TRUE, level is set to seq(51,99,by=3). This is suitable for fan plots.  |
| h       | Number of periods for forecasting. Ignored if newdata present.   |
| lambda  | Box-Cox transformation parameter. Ignored if NULL. Otherwise, forecasts back-transformed via an inverse Box-Cox transformation.  |
| biasadj | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities.  |
| ts      | If TRUE, the forecasts will be treated as time series provided the original data is a time series; the newdata will be interpreted as related to the subsequent time periods. If FALSE, any time series attributes of the original data will be ignored. |
| ...     | Other arguments passed to <a href="#">predict.lm()</a> .   |

**Details**

forecast.lm is largely a wrapper for [predict.lm\(\)](#) except that it allows variables "trend" and "season" which are created on the fly from the time series characteristics of the data. Also, the output is reformatted into a forecast object.

**Value**

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `forecast.lm`.

An object of class "forecast" is a list containing at least the following elements:

|                        |   |
|------------------------|---|
| <code>model</code>     | A list containing information about the fitted model            |
| <code>method</code>    | The name of the forecasting method as a character string        |
| <code>mean</code>      | Point forecasts as a time series                                |
| <code>lower</code>     | Lower limits for prediction intervals                           |
| <code>upper</code>     | Upper limits for prediction intervals                           |
| <code>level</code>     | The confidence values associated with the prediction intervals  |
| <code>x</code>         | The historical data for the response variable.                  |
| <code>residuals</code> | Residuals from the fitted model. That is x minus fitted values. |
| <code>fitted</code>    | Fitted values   |

**Author(s)**

Rob J Hyndman

**See Also**

[tslm](#), [lm](#).

**Examples**

```
y <- ts(rnorm(120,0,3) + 1:120 + 20*sin(2*pi*(1:120)/12), frequency=12)
fit <- tslm(y ~ trend + season)
plot(forecast(fit, h=20))
```

---

forecast.mlm

*Forecast a multiple linear model with possible time series components*

---

**Description**

`forecast.mlm` is used to predict multiple linear models, especially those involving trend and seasonality components.

**Usage**

```
## S3 method for class 'mlm'
forecast(object, newdata, h = 10, level = c(80, 95),
         fan = FALSE, lambda = object$lambda, biasadj = FALSE, ts = TRUE, ...)
```

**Arguments**

|         |  |
|---------|--|
| object  | Object of class "mlm", usually the result of a call to <code>lm</code> or <code>tslm</code> .  |
| newdata | An optional data frame in which to look for variables with which to predict. If omitted, it is assumed that the only variables are trend and season, and h forecasts are produced.   |
| level   | Confidence level for prediction intervals.   |
| fan     | If TRUE, level is set to <code>seq(51,99,by=3)</code> . This is suitable for fan plots.  |
| h       | Number of periods for forecasting. Ignored if newdata present.   |
| lambda  | Box-Cox transformation parameter. Ignored if NULL. Otherwise, forecasts back-transformed via an inverse Box-Cox transformation.  |
| biasadj | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities.  |
| ts      | If TRUE, the forecasts will be treated as time series provided the original data is a time series; the newdata will be interpreted as related to the subsequent time periods. If FALSE, any time series attributes of the original data will be ignored. |
| ...     | Other arguments passed to <code>forecast.lm()</code> .   |

**Details**

`forecast.mlm` is largely a wrapper for `forecast.lm()` except that it allows forecasts to be generated on multiple series. Also, the output is reformatted into a `mforecast` object.

**Value**

An object of class "mforecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `forecast.lm`.

An object of class "mforecast" is a list containing at least the following elements:

|           |   |
|-----------|---|
| model     | A list containing information about the fitted model            |
| method    | The name of the forecasting method as a character string        |
| mean      | Point forecasts as a multivariate time series                   |
| lower     | Lower limits for prediction intervals of each series            |
| upper     | Upper limits for prediction intervals of each series            |
| level     | The confidence values associated with the prediction intervals  |
| x         | The historical data for the response variable.                  |
| residuals | Residuals from the fitted model. That is x minus fitted values. |
| fitted    | Fitted values   |

lungDeaths <- cbind(mdeaths, fdeaths)
fit <- tslm(lungDeaths ~ trend + season)
fcast <- forecast(fit, h=10)

carPower <- as.matrix(mtcars[,c("qsec", "hp")])
carmpg <- mtcars[, "mpg"]
fit <- lm(carPower ~ carmpg)
fcast <- forecast(fit, newdata=data.frame(carmpg=30))
```

---

forecast.nnetar

*Forecasting using neural network models*

---

**Description**

Returns forecasts and other information for univariate neural network models.

**Usage**

```
## S3 method for class 'nnetar'
forecast(object, h=ifelse(object$m > 1, 2 * object$m, 10),
         PI=FALSE, level=c(80, 95), fan=FALSE, xreg=NULL,
         lambda=object$lambda, bootstrap=FALSE, npaths=1000, innov=NULL, ...)
```

**Arguments**

|        |   |
|--------|---|
| object | An object of class "nnetar" resulting from a call to <a href="#">arima</a> .  |
| h      | Number of periods for forecasting. If xreg is used, h is ignored and the number of forecast periods is set to the number of rows of xreg.                         |
| PI     | If TRUE, prediction intervals are produced, otherwise only point forecasts are calculated. If PI is FALSE, then level, fan, bootstrap and npaths are all ignored. |
| level  | Confidence level for prediction intervals.  |
| fan    | If TRUE, level is set to seq(51, 99, by=3). This is suitable for fan plots.   |
| xreg   | Future values of external regressor variables.  |
| lambda | Box-Cox transformation parameter. Ignored if NULL. Otherwise, forecasts back-transformed via an inverse Box-Cox transformation.                                   |

|           |   |
|-----------|---|
| bootstrap | If TRUE, then prediction intervals computed using simulations with resampled residuals rather than normally distributed errors. Ignored if innov is not NULL.                 |
| npaths    | Number of sample paths used in computing simulated prediction intervals.  |
| innov     | Values to use as innovations for prediction intervals. Must be a matrix with h rows and npaths columns (vectors are coerced into a matrix). If present, bootstrap is ignored. |
| ...       | Additional arguments passed to <a href="#">simulate.nnetar</a>  |

### Details

Prediction intervals are calculated through simulations and can be slow. Note that if the network is too complex and overfits the data, the residuals can be arbitrarily small; if used for prediction interval calculations, they could lead to misleadingly small values.

### Value

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `forecast.nnetar`.

An object of class "forecast" is a list containing at least the following elements:

|           |   |
|-----------|---|
| model     | A list containing information about the fitted model  |
| method    | The name of the forecasting method as a character string  |
| mean      | Point forecasts as a time series  |
| lower     | Lower limits for prediction intervals   |
| upper     | Upper limits for prediction intervals   |
| level     | The confidence values associated with the prediction intervals  |
| x         | The original time series (either object itself or the time series used to create the model stored as object). |
| xreg      | The external regressors used in fitting (if given).   |
| residuals | Residuals from the fitted model. That is x minus fitted values.   |
| fitted    | Fitted values (one-step forecasts)  |
| ...       | Other arguments   |

forecast.stl

*Forecasting using stl objects*

---

**Description**

Forecasts of STL objects are obtained by applying a non-seasonal forecasting method to the seasonally adjusted data and re-seasonalizing using the last year of the seasonal component.

**Usage**

```
stlm(y, s.window=7, robust=FALSE, method=c("ets", "arma"),
      modelfunction=NULL, etsmodel="ZZN", lambda=NULL, xreg=NULL,
      allow.multiplicative.trend=FALSE, x=y, ...)
stlf(y, h=frequency(x)*2, s.window=7, t.window=NULL, robust=FALSE,
      lambda=NULL, biasadj=FALSE, x=y, ...)
## S3 method for class 'stlm'
forecast(object, h = 2*object$m,
         level = c(80, 95), fan = FALSE, lambda=object$lambda, biasadj=FALSE, newxreg=NULL,
         allow.multiplicative.trend=FALSE, ...)
## S3 method for class 'stl'
forecast(object, method=c("ets", "arma", "naive", "rwdrift"),
         etsmodel="ZZN", forecastfunction=NULL,
         h=frequency(object$time.series)*2, level=c(80, 95),
         fan=FALSE, lambda=NULL, biasadj=FALSE, xreg=NULL, newxreg=NULL,
         allow.multiplicative.trend=FALSE, ...)
```

**Arguments**

|                               |  |
|-------------------------------|--|
| <code>y</code>                | A univariate numeric time series of class <code>ts</code>  |
| <code>object</code>           | An object of class <code>stl</code> or <code>stlm</code> . Usually the result of a call to <code>stl</code> or <code>stlm</code> .   |
| <code>method</code>           | Method to use for forecasting the seasonally adjusted series.  |
| <code>modelfunction</code>    | An alternative way of specifying the function for modelling the seasonally adjusted series. If <code>modelfunction</code> is not <code>NULL</code> , then <code>method</code> is ignored. Otherwise <code>method</code> is used to specify the time series model to be used.       |
| <code>forecastfunction</code> | An alternative way of specifying the function for forecasting the seasonally adjusted series. If <code>forecastfunction</code> is not <code>NULL</code> , then <code>method</code> is ignored. Otherwise <code>method</code> is used to specify the forecasting method to be used. |
| <code>etsmodel</code>         | The ets model specification passed to <code>ets</code> . By default it allows any non-seasonal model. If <code>method!="ets"</code> , this argument is ignored.  |

|                            |   |
|----------------------------|---|
| xreg                       | Historical regressors to be used in <code>auto.arima()</code> when <code>method=="arima"</code> .   |
| newxreg                    | Future regressors to be used in <code>forecast.Arima()</code> .   |
| h                          | Number of periods for forecasting.  |
| level                      | Confidence level for prediction intervals.  |
| fan                        | If TRUE, level is set to <code>seq(51,99,by=3)</code> . This is suitable for fan plots.   |
| lambda                     | Box-Cox transformation parameter. Ignored if NULL. Otherwise, data transformed before decomposition and back-transformed after forecasts are computed.  |
| biasadj                    | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities. |
| s.window                   | Either the character string "periodic" or the span (in lags) of the loess window for seasonal extraction.   |
| t.window                   | A number to control the smoothness of the trend. See <code>stl</code> for details.  |
| robust                     | If TRUE, robust fitting will used in the loess procedure within <code>stl</code> .  |
| allow.multiplicative.trend | If TRUE, then ETS models with multiplicative trends are allowed. Otherwise, only additive or no trend ETS models are permitted.   |
| x                          | Deprecated. Included for backwards compatibility.   |
| ...                        | Other arguments passed to <code>forecast.stl</code> , <code>modelfunction</code> or <code>forecastfunction</code> .   |

## Details

`stlm` takes a time series `y`, applies an STL decomposition, and models the seasonally adjusted data using the model passed as `modelfunction` or specified using `method`. It returns an object that includes the original STL decomposition and a time series model fitted to the seasonally adjusted data. This object can be passed to the `forecast.stlm` for forecasting.

`forecast.stlm` forecasts the seasonally adjusted data, then re-seasonalizes the results by adding back the last year of the estimated seasonal component.

`stlf` combines `stlm` and `forecast.stlm`. It takes a `ts` argument, applies an STL decomposition, models the seasonally adjusted data, reseasonalizes, and returns the forecasts. However, it allows more general forecasting methods to be specified via `forecastfunction`.

`forecast.stl` is similar to `stlf` except that it takes the STL decomposition as the first argument, instead of the time series.

Note that the prediction intervals ignore the uncertainty associated with the seasonal component. They are computed using the prediction intervals from the seasonally adjusted series, which are then reseasonalized using the last year of the seasonal component. The uncertainty in the seasonal component is ignored.

The time series model for the seasonally adjusted data can be specified in `stlm` using either `method` or `modelfunction`. The `method` argument provides a shorthand way of specifying `modelfunction` for a few special cases. More generally, `modelfunction` can be any function with first argument a `ts` object, that returns an object that can be passed to `forecast`. For example, `forecastfunction=ar` uses the `ar` function for modelling the seasonally adjusted series.

The forecasting method for the seasonally adjusted data can be specified in `stlf` and `forecast.stl` using either method or `forecastfunction`. The `method` argument provides a shorthand way of specifying `forecastfunction` for a few special cases. More generally, `forecastfunction` can be any function with first argument a `ts` object, and other `h` and `level`, which returns an object of class `forecast`. For example, `forecastfunction=thetaf` uses the `thetaf` function for forecasting the seasonally adjusted series.

### Value

`stlm` returns an object of class `stlm`. The other functions return objects of class `forecast`.

There are many methods for working with `forecast` objects including `summary` to obtain and print a summary of the results, while `plot` produces a plot of the forecasts and prediction intervals. The generic accessor functions `fitted.values` and `residuals` extract useful features.

### Examples

```
tsmod <- stlm(USAccDeaths, modelfunction=ar)
plot(forecast(tsmod, h=36))

plot(stlf(AirPassengers, lambda=0))

decomp <- stl(USAccDeaths, s.window="periodic")
plot(forecast(decomp))
```

---

forecast.StructTS      *Forecasting using Structural Time Series models*

---

### Description

Returns forecasts and other information for univariate structural time series models.

### Usage

```
## S3 method for class 'StructTS'
forecast(object,
  h=ifelse(object$coef["epsilon"] > 1e-10, 2*object$xtsp[3],10),
  level=c(80,95), fan=FALSE, lambda=NULL, biasadj=FALSE, ...)
```

**Arguments**

|         |   |
|---------|---|
| object  | An object of class "StructTS". Usually the result of a call to <a href="#">StructTS</a> .   |
| h       | Number of periods for forecasting   |
| level   | Confidence level for prediction intervals.  |
| fan     | If TRUE, level is set to seq(51,99,by=3). This is suitable for fan plots.   |
| lambda  | Box-Cox transformation parameter. Ignored if NULL. Otherwise, forecasts back-transformed via an inverse Box-Cox transformation.   |
| biasadj | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities. |
| ...     | Other arguments.  |

**Details**

This function calls `predict.StructTS` and constructs an object of class "forecast" from the results.

**Value**

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `forecast.StructTS`.

An object of class "forecast" is a list containing at least the following elements:

|           |   |
|-----------|---|
| model     | A list containing information about the fitted model  |
| method    | The name of the forecasting method as a character string  |
| mean      | Point forecasts as a time series  |
| lower     | Lower limits for prediction intervals   |
| upper     | Upper limits for prediction intervals   |
| level     | The confidence values associated with the prediction intervals  |
| x         | The original time series (either object itself or the time series used to create the model stored as object). |
| residuals | Residuals from the fitted model. That is x minus fitted values.   |
| fitted    | Fitted values (one-step forecasts)  |

**Author(s)**

Rob J Hyndman

plot(forecast(fit))
```

---

|                  |   |
|------------------|---|
| fortify.forecast | <i>Fortify a forecast object to data.frame for ggplot</i> |
|------------------|---|

---

## Description

fortify.forecast takes a forecast object and converts it into a data frame (for usage with ggplot2).

## Usage

```
## S3 method for class 'forecast'
fortify(model, data=as.data.frame(model), PI=TRUE, ...)
```

## Arguments

|       |  |
|-------|--|
| model | Object of class “ts” to be converted to “data.frame”.  |
| data  | Not used (required for <a href="#">fortify</a> method) |
| PI    | If TRUE, confidence intervals are included.            |
| ...   | Other arguments, currently ignored.                    |

## Value

A data.frame containing elements from a forecast object necessary for plotting in ggplot.

**Description**

Australian monthly gas production: 1956–1995.

**Usage**

gas

**Format**

Time series data

**Source**

Australian Bureau of Statistics.

**Examples**

```
plot(gas)
seasonplot(gas)
tsdisplay(gas)
```

---

|               |                      |
|---------------|----------------------|
| geom_forecast | <i>Forecast plot</i> |
|---------------|----------------------|

---

**Description**

Generates forecasts from `forecast.ts` and adds them to the plot. Forecasts can be modified via sending forecast specific arguments above.

Multivariate forecasting is supported by having each time series on a different group.

You can also pass `geom_forecast` a forecast object to add it to the plot.

The aesthetics required for the forecasting to work includes forecast observations on the y axis, and the time of the observations on the x axis. Refer to the examples below. To automatically set up aesthetics, use `autoplot`.

**Usage**

```
geom_forecast(mapping = NULL, data = NULL, stat = "forecast",
  position = "identity", na.rm = FALSE, show.legend = NA,
  inherit.aes = TRUE, plot.conf=TRUE, h=NULL, level=c(80,95), fan=FALSE,
  robust=FALSE, lambda=NULL, find.frequency=FALSE,
  allow.multiplicative.trend=FALSE, series, ...)
```

**Arguments**

|                            |   |
|----------------------------|---|
| mapping                    | Set of aesthetic mappings created by <a href="#">aes</a> or <a href="#">aes_</a> . If specified and <code>inherit.aes = TRUE</code> (the default), it is combined with the default mapping at the top level of the plot. You must supply mapping if there is no plot mapping.   |
| data                       | The data to be displayed in this layer. There are three options:<br>If <code>NULL</code> , the default, the data is inherited from the plot data as specified in the call to <a href="#">ggplot</a> .<br>A <code>data.frame</code> , or other object, will override the plot data. All objects will be fortified to produce a data frame. See <a href="#">fortify</a> for which variables will be created.<br>A function will be called with a single argument, the plot data. The return value must be a <code>data.frame</code> , and will be used as the layer data. |
| stat                       | The stat object to use calculate the data.  |
| position                   | Position adjustment, either as a string, or the result of a call to a position adjustment function.   |
| na.rm                      | If <code>FALSE</code> (the default), removes missing values with a warning. If <code>TRUE</code> silently removes missing values.   |
| show.legend                | logical. Should this layer be included in the legends? <code>NA</code> , the default, includes if any aesthetics are mapped. <code>FALSE</code> never includes, and <code>TRUE</code> always includes.  |
| inherit.aes                | If <code>FALSE</code> , overrides the default aesthetics, rather than combining with them. This is most useful for helper functions that define both data and aesthetics and shouldn't inherit behaviour from the default plot specification, e.g. <a href="#">borders</a> .  |
| plot.conf                  | If <code>FALSE</code> , confidence intervals will not be plotted, giving only the forecast line.  |
| h                          | Number of periods for forecasting   |
| level                      | Confidence level for prediction intervals.  |
| fan                        | If <code>TRUE</code> , <code>level</code> is set to <code>seq(51, 99, by=3)</code> . This is suitable for fan plots.  |
| robust                     | If <code>TRUE</code> , the function is robust to missing values and outliers in object. This argument is only valid when object is of class <code>ts</code> .   |
| lambda                     | Box-Cox transformation parameter.   |
| find.frequency             | If <code>TRUE</code> , the function determines the appropriate period, if the data is of unknown period.  |
| allow.multiplicative.trend | If <code>TRUE</code> , then ETS models with multiplicative trends are allowed. Otherwise, only additive or no trend ETS models are permitted.   |
| series                     | Matches an unidentified forecast layer with a coloured object on the plot.  |
| ...                        | other arguments passed on to <a href="#">layer</a> . These are often aesthetics, used to set an aesthetic to a fixed value, like <code>color = "red"</code> or <code>alpha = .5</code> . They may also be parameters to the paired <code>geom/stat</code> .   |

**Value**

A layer for a `ggplot` graph.

---

`getResponse`*Get response variable from time series model.*

---

**Description**

`getResponse` is a generic function for extracting the historical data from a time series model (including Arima, ets, ar, fracdiff), a linear model of class `lm`, or a forecast object. The function invokes particular *methods* which depend on the class of the first argument.

**Usage**

```
getResponse(object, ...)
```

**Arguments**

object            a time series model or forecast object.  
 ...              Additional arguments that are ignored.

**Value**

A numerical vector or a time series object of class `ts`.

**Author(s)**

Rob J Hyndman

---

gglagplot

*Time series lag ggplots*

---

**Description**

Plots a lag plot using `ggplot`.

“`gglagplot`” will plot time series against lagged versions of themselves. Helps visualising ‘auto-dependence’ even when auto-correlations vanish.

“`gglagchull`” will layer convex hulls of the lags, layered on a single plot. This helps visualise the change in ‘auto-dependence’ as lags increase.

**Usage**

```
gglagplot(x, lags = 1, set.lags = 1:lags, diag=TRUE,
          diag.col="gray", do.lines = TRUE, colour = TRUE, continuous = TRUE,
          labels = FALSE, seasonal = TRUE, ...)
gglagchull(x, lags = 1, set.lags = 1:lags, diag=TRUE,
           diag.col="gray", ...)
```

**Arguments**

`x`                a time series object (type `ts`).

`lags`             number of lag plots desired, see arg `set.lags`.

`set.lags`         vector of positive integers specifying which lags to use.

`diag`             logical indicating if the `x=y` diagonal should be drawn.

`diag.col`         color to be used for the diagonal if(`diag`).

`do.lines`         if `TRUE`, lines will be drawn, otherwise points will be drawn.

`colour`           logical indicating if lines should be coloured.

`continuous`      Should the colour scheme for years be continuous or discrete?

`labels`           logical indicating if labels should be used.

`seasonal`         Should the line colour be based on seasonal characteristics (`TRUE`), or sequential (`FALSE`).

...                Not used (for consistency with `lag.plot`)

**Value**

None.

**Author(s)**

Mitchell O'Hara-Wild

lungDeaths <- cbind(mdeaths, fdeaths)
gglagplot(lungDeaths, lags=2)
gglagchull(lungDeaths, lags=6)
```

---

ggmonthplot

*Create a seasonal subseries ggplot*

---

**Description**

Plots a month plot using ggplot.

**Usage**

```
ggmonthplot(x, labels = NULL, times = time(x), phase = cycle(x), ...)
```

**Arguments**

|        |   |
|--------|---|
| x      | a time series object (type ts).             |
| labels | A vector of labels to use for each 'season' |
| times  | A vector of times for each observation      |
| phase  | A vector of seasonal components             |
| ...    | Not used (for consistency with monthplot)   |

**Value**

None.

```

---

**ma** *Moving-average smoothing*

---

**Description**

ma computes a simple moving average smoother of a given time series.

**Usage**

```
ma(x, order, centre=TRUE)
```

**Arguments**

|        |  |
|--------|--|
| x      | Univariate time series                                       |
| order  | Order of moving average smoother                             |
| centre | If TRUE, then the moving average is centred for even orders. |

**Details**

The moving average smoother averages the nearest order periods of each observation. As neighbouring observations of a time series are likely to be similar in value, averaging eliminates some of the randomness in the data, leaving a smooth trend-cycle component.

$$\hat{T}_t = \frac{1}{m} \sum_{j=-k}^k y_{t+j}$$

where  $k = \frac{m-1}{2}$

When an even order is specified, the observations averaged will include one more observation from the future than the past (k is rounded up). If centre is TRUE, the value from two moving averages (where k is rounded up and down respectively) are averaged, centering the moving average.

**Value**

Numerical time series object containing the simple moving average smoothed values.

```

---

|       |                      |
|-------|----------------------|
| meanf | <i>Mean Forecast</i> |
|-------|----------------------|

---

### Description

Returns forecasts and prediction intervals for an iid model applied to  $y$ .

### Usage

```
meanf(y, h=10, level=c(80,95), fan=FALSE, lambda=NULL, biasadj=FALSE, x=y)
```

### Arguments

|         |   |
|---------|---|
| $y$     | a numeric vector or time series   |
| $h$     | Number of periods for forecasting   |
| level   | Confidence levels for prediction intervals.   |
| fan     | If TRUE, level is set to seq(51,99,by=3). This is suitable for fan plots.   |
| lambda  | Box-Cox transformation parameter. Ignored if NULL. Otherwise, forecasts back-transformed via an inverse Box-Cox transformation.   |
| biasadj | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities. |
| $x$     | Deprecated. Included for backwards compatibility.   |

### Details

The iid model is

$$Y_t = \mu + Z_t$$

where  $Z_t$  is a normal iid error. Forecasts are given by

$$Y_n(h) = \mu$$

where  $\mu$  is estimated by the sample mean.

### Value

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `meanf`.

An object of class "forecast" is a list containing at least the following elements:

|        |  |
|--------|--|
| model  | A list containing information about the fitted model     |
| method | The name of the forecasting method as a character string |

|           |   |
|-----------|---|
| mean      | Point forecasts as a time series  |
| lower     | Lower limits for prediction intervals   |
| upper     | Upper limits for prediction intervals   |
| level     | The confidence values associated with the prediction intervals  |
| x         | The original time series (either object itself or the time series used to create the model stored as object). |
| residuals | Residuals from the fitted model. That is x minus fitted values.   |
| fitted    | Fitted values (one-step forecasts)  |

**Author(s)**

Rob J Hyndman

**See Also**

```
nile.fcast <- meanf(Nile, h=10)
plot(nile.fcast)
```

---

mforecast

*Forecasting time series*

---

**Description**

mforecast is a class of objects for forecasting from multivariate time series or multivariate time series models. The function invokes particular *methods* which depend on the class of the first argument.

For example, the function [forecast.mlm](#) makes multivariate forecasts based on the results produced by [tslm](#).

**Usage**

```
## S3 method for class 'mts'
forecast(object, h=ifelse(frequency(object)>1, 2*frequency(object), 10),
         level=c(80,95), fan=FALSE, robust=FALSE, lambda = NULL, find.frequency = FALSE,
         allow.multiplicative.trend=FALSE, ...)
```

**Arguments**

|                            |  |
|----------------------------|--|
| object                     | a multivariate time series or multivariate time series model for which forecasts are required                                      |
| h                          | Number of periods for forecasting  |
| level                      | Confidence level for prediction intervals.   |
| fan                        | If TRUE, level is set to seq(51, 99, by=3). This is suitable for fan plots.  |
| robust                     | If TRUE, the function is robust to missing values and outliers in object. This argument is only valid when object is of class mts. |
| lambda                     | Box-Cox transformation parameter.  |
| find.frequency             | If TRUE, the function determines the appropriate period, if the data is of unknown period.   |
| allow.multiplicative.trend | If TRUE, then ETS models with multiplicative trends are allowed. Otherwise, only additive or no trend ETS models are permitted.    |
| ...                        | Additional arguments affecting the forecasts produced.   |

**Value**

An object of class "mforecast".

The function summary is used to obtain and print a summary of the results, while the function plot produces a plot of the multivariate forecasts and prediction intervals.

The generic accessors functions fitted.values and residuals extract various useful features of the value returned by forecast\$model.

An object of class "mforecast" is a list usually containing at least the following elements:

|           |  |
|-----------|--|
| model     | A list containing information about the fitted model   |
| method    | The name of the forecasting method as a character string   |
| mean      | Point forecasts as a time series   |
| lower     | Lower limits for prediction intervals  |
| upper     | Upper limits for prediction intervals  |
| level     | The confidence values associated with the prediction intervals   |
| x         | The original time series (either object itself or the time series used to create the model stored as object).      |
| residuals | Residuals from the fitted model. For models with additive errors, the residuals will be x minus the fitted values. |
| fitted    | Fitted values (one-step forecasts)   |

plot(ldeaths.adj,xlab="Year",ylab="pounds",
     main="Adjusted monthly deaths from lung disease (UK)")
```

---

`msts`*Multi-Seasonal Time Series*

---

**Description**

`msts` is an S3 class for multi seasonal time series objects, intended to be used for models that support multiple seasonal periods. The `msts` class inherits from the `ts` class and has an additional "msts" attribute which contains the vector of seasonal periods. All methods that work on a `ts` class, should also work on a `msts` class.

**Usage**

```
msts(data, seasonal.periods, ts.frequency=floor(max(seasonal.periods)),
     ... )
```

**Arguments**

|                               |   |
|-------------------------------|---|
| <code>data</code>             | A numeric vector, <code>ts</code> object, matrix or data frame. It is intended that the time series data is univariate, otherwise treated the same as <code>ts()</code> . |
| <code>seasonal.periods</code> | A vector of the seasonal periods of the <code>msts</code> .   |
| <code>ts.frequency</code>     | The seasonal period that should be used as frequency of the underlying <code>ts</code> object. The default value is <code>max(seasonal.periods)</code> .                  |
| <code>...</code>              | Arguments to be passed to the underlying call to <code>ts()</code> . For example <code>start=c(1987, 5)</code> .  |

**Value**

An object of class `c("msts", "ts")`. If there is only one seasonal period (i.e., `length(seasonal.periods)==1`), then the object is of class "ts".

**Author(s)**

Slava Razbash and Rob J Hyndman

**Examples**

```
x <- msts(taylor, seasonal.periods=c(48,336), start=2000+22/52)
y <- msts(USAccDeaths, seasonal.periods=12, start=1949)
```

---

|           |  |
|-----------|--|
| na.interp | <i>Interpolate missing values in a time series</i> |
|-----------|--|

---

**Description**

Uses linear interpolation for non-seasonal series and a periodic stl decomposition with seasonal series to replace missing values.

**Usage**

```
na.interp(x, lambda = NULL)
```

**Arguments**

|        |   |
|--------|---|
| x      | time series                                       |
| lambda | a numeric value suggesting Box-cox transformation |

**Details**

A more general and flexible approach is available using `na.approx` in the zoo package.

**Value**

Time series

**Author(s)**

Rob J Hyndman

**See Also**

[na.interp](#), [tsoutliers](#)

**Examples**

```
data(gold)
plot(na.interp(gold))
```

**Description**

`rwf()` returns forecasts and prediction intervals for a random walk with drift model applied to  $y$ . This is equivalent to an ARIMA(0,1,0) model with an optional drift coefficient. `naive()` is simply a wrapper to `rwf()` for simplicity. `snaive()` returns forecasts and prediction intervals from an ARIMA(0,0,0)(0,1,0) $m$  model where  $m$  is the seasonal period.

**Usage**

```
naive(y, h=10, level=c(80,95), fan=FALSE, lambda=NULL, biasadj=FALSE, x=y)
rwf(y, h=10, drift=FALSE, level=c(80,95), fan=FALSE, lambda=NULL, biasadj=FALSE, x=y)
snaive(y, h=2*frequency(x), level=c(80,95), fan=FALSE, lambda=NULL, biasadj=FALSE, x=y)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>y</code>       | a numeric vector or time series   |
| <code>h</code>       | Number of periods for forecasting   |
| <code>drift</code>   | Logical flag. If TRUE, fits a random walk with drift model.   |
| <code>level</code>   | Confidence levels for prediction intervals.   |
| <code>fan</code>     | If TRUE, level is set to <code>seq(51,99,by=3)</code> . This is suitable for fan plots.   |
| <code>lambda</code>  | Box-Cox transformation parameter. Ignored if NULL. Otherwise, forecasts back-transformed via an inverse Box-Cox transformation.   |
| <code>biasadj</code> | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities. |
| <code>x</code>       | Deprecated. Included for backwards compatibility.   |

**Details**

The random walk with drift model is

$$Y_t = c + Y_{t-1} + Z_t$$

where  $Z_t$  is a normal iid error. Forecasts are given by

$$Y_n(h) = ch + Y_n$$

. If there is no drift (as in `naive`), the drift parameter  $c=0$ . Forecast standard errors allow for uncertainty in estimating the drift parameter.

The seasonal naive model is

$$Y_t = Y_{t-m} + Z_t$$

where  $Z_t$  is a normal iid error.

**Value**

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `naive` or `snaive`.

An object of class "forecast" is a list containing at least the following elements:

|                        |   |
|------------------------|---|
| <code>model</code>     | A list containing information about the fitted model  |
| <code>method</code>    | The name of the forecasting method as a character string  |
| <code>mean</code>      | Point forecasts as a time series  |
| <code>lower</code>     | Lower limits for prediction intervals   |
| <code>upper</code>     | Upper limits for prediction intervals   |
| <code>level</code>     | The confidence values associated with the prediction intervals  |
| <code>x</code>         | The original time series (either object itself or the time series used to create the model stored as object). |
| <code>residuals</code> | Residuals from the fitted model. That is <code>x</code> minus fitted values.                                  |
| <code>fitted</code>    | Fitted values (one-step forecasts)  |

```

---

ndiffs

*Number of differences required for a stationary series*

---

**Description**

Functions to estimate the number of differences required to make a given time series stationary. `ndiffs` estimates the number of first differences and `nsdiffs` estimates the number of seasonal differences.

**Usage**

```
ndiffs(x, alpha=0.05, test=c("kpss", "adf", "pp"), max.d=2)
nsdiffs(x, m=frequency(x), test=c("ocsb", "ch"), max.D=1)
```

**Arguments**

|       |  |
|-------|--|
| x     | A univariate time series                           |
| alpha | Level of the test                                  |
| m     | Length of seasonal period                          |
| test  | Type of unit root test to use                      |
| max.d | Maximum number of non-seasonal differences allowed |
| max.D | Maximum number of seasonal differences allowed     |

**Details**

ndiffs uses a unit root test to determine the number of differences required for time series  $x$  to be made stationary. If `test="kpss"`, the KPSS test is used with the null hypothesis that  $x$  has a stationary root against a unit-root alternative. Then the test returns the least number of differences required to pass the test at the level  $\alpha$ . If `test="adf"`, the Augmented Dickey-Fuller test is used and if `test="pp"` the Phillips-Perron test is used. In both of these cases, the null hypothesis is that  $x$  has a unit root against a stationary root alternative. Then the test returns the least number of differences required to fail the test at the level  $\alpha$ .

nsdiffs uses seasonal unit root tests to determine the number of seasonal differences required for time series  $x$  to be made stationary (possibly with some lag-one differencing as well). If `test="ch"`, the Canova-Hansen (1995) test is used (with null hypothesis of deterministic seasonality) and if `test="ocsb"`, the Osborn-Chui-Smith-Birchenhall (1988) test is used (with null hypothesis that a seasonal unit root exists).

**Value**

An integer.

nnetar

*Neural Network Time Series Forecasts*

---

### Description

Feed-forward neural networks with a single hidden layer and lagged inputs for forecasting univariate time series.

### Usage

```
nnetar(y, p, P=1, size, repeats=20, xreg=NULL, lambda=NULL, model=NULL,
       subset=NULL, scale.inputs=TRUE, x=y, ...)
```

### Arguments

|         |   |
|---------|---|
| y       | A numeric vector or time series.  |
| p       | Embedding dimension for non-seasonal time series. Number of non-seasonal lags used as inputs. For non-seasonal time series, the default is the optimal number of lags (according to the AIC) for a linear AR(p) model. For seasonal time series, the same method is used but applied to seasonally adjusted data (from an stl decomposition). |
| P       | Number of seasonal lags used as inputs.   |
| size    | Number of nodes in the hidden layer. Default is half of the number of input nodes (including external regressors, if given) plus 1.   |
| repeats | Number of networks to fit with different random starting weights. These are then averaged when producing forecasts.   |
| xreg    | Optionally, a vector or matrix of external regressors, which must have the same number of rows as y. Must be numeric.   |
| lambda  | Box-Cox transformation parameter.   |
| model   | Output from a previous call to nnetar. If model is passed, this same model is fitted to y without re-estimating any parameters.   |

|              |   |
|--------------|---|
| subset       | Optional vector specifying a subset of observations to be used in the fit. Can be an integer index vector or a logical vector the same length as <i>y</i> . All observations are used by default. |
| scale.inputs | If TRUE, inputs are scaled by subtracting the column means and dividing by their respective standard deviations. If <i>lambda</i> is not NULL, scaling is applied after Box-Cox transformation.   |
| x            | Deprecated. Included for backwards compatibility.   |
| ...          | Other arguments passed to <a href="#">nnet</a> for <i>nnetar</i> .  |

### Details

A feed-forward neural network is fitted with lagged values of *y* as inputs and a single hidden layer with *size* nodes. The inputs are for lags 1 to *p*, and lags *m* to *mP* where  $m = \text{frequency}(y)$ . If there are missing values in *y* or *xreg*, the corresponding rows (and any others which depend on them as lags) are omitted from the fit. A total of *repeats* networks are fitted, each with random starting weights. These are then averaged when computing forecasts. The network is trained for one-step forecasting. Multi-step forecasts are computed recursively.

For non-seasonal data, the fitted model is denoted as an NNAR(*p*,*k*) model, where *k* is the number of hidden nodes. This is analogous to an AR(*p*) model but with nonlinear functions. For seasonal data, the fitted model is called an NNAR(*p*,*P*,*k*)[*m*] model, which is analogous to an ARIMA(*p*,0,0)(*P*,0,0)[*m*] model but with nonlinear functions.

### Value

Returns an object of class "nnetar".

The function `summary` is used to obtain and print a summary of the results.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by *nnetar*.

|           |  |
|-----------|--|
| model     | A list containing information about the fitted model                   |
| method    | The name of the forecasting method as a character string               |
| x         | The original time series.  |
| xreg      | The external regressors used in fitting (if given).                    |
| residuals | Residuals from the fitted model. That is <i>x</i> minus fitted values. |
| fitted    | Fitted values (one-step forecasts)                                     |
| ...       | Other arguments  |

**Examples**

```

fit <- nnetar(lynx)
fcast <- forecast(fit)
plot(fcast)

## Arguments can be passed to nnet()
fit <- nnetar(lynx, decay=0.5, maxit=150)
plot(forecast(fit))
lines(lynx)

## Fit model to first 100 years of lynx data
fit <- nnetar(window(lynx,end=1920), decay=0.5, maxit=150)
plot(forecast(fit,h=14))
lines(lynx)

## Apply fitted model to later data, including all optional arguments
fit2 <- nnetar(window(lynx,start=1921), model=fit)

```

---

plot.Arima

*Plot characteristic roots from ARIMA model*

---

**Description**

Produces a plot of the inverse AR and MA roots of an ARIMA model. Inverse roots outside the unit circle are shown in red.

autoplot will produce an equivalent plot as a ggplot object.

**Usage**

```

## S3 method for class 'Arima'
plot(x, type=c("both","ar","ma"),
     main, xlab="Real", ylab="Imaginary", ...)
## S3 method for class 'Arima'
autoplot(object, type=c("both","ar","ma"), ...)
## S3 method for class 'ar'
plot(x, main, xlab="Real", ylab="Imaginary", ...)

```

**Arguments**

|        |  |
|--------|--|
| x      | Object of class "Arima" or "ar".   |
| object | Object of class "Arima" or "ar". Used for ggplot graphics (S3 method consistency). |
| type   | Determines if both AR and MA roots are plotted, or if just one set is plotted.     |
| main   | Main title. Default is "Inverse AR roots" or "Inverse MA roots".                   |
| xlab   | X-axis label.  |
| ylab   | Y-axis label.  |
| ...    | Other plotting parameters passed to <a href="#">par</a> .                          |

**Value**

None. Function produces a plot

plot(fit)
autoplot(fit)

plot(ar.ols(gold[1:61]))
autoplot(ar.ols(gold[1:61]))
```

---

plot.bats

*Plot components from BATS model*

---

**Description**

Produces a plot of the level, slope and seasonal components from a BATS or TBATS model.

**Usage**

```
## S3 method for class 'bats'
plot(x, main="Decomposition by BATS model", ...)
## S3 method for class 'tbats'
plot(x, main="Decomposition by TBATS model", ...)
```

**Arguments**

|      |   |
|------|---|
| x    | Object of class "ets".                                    |
| main | Main title for plot.                                      |
| ...  | Other plotting parameters passed to <a href="#">par</a> . |

plot.ets

*Plot components from ETS model*

---

**Description**

Produces a plot of the level, slope and seasonal components from an ETS model.  
autoplot will produce an equivalent plot as a ggplot object.

**Usage**

```
## S3 method for class 'ets'  
plot(x, ...)  
## S3 method for class 'ets'  
autoplot(object, ...)
```

**Arguments**

|        |  |
|--------|--|
| x      | Object of class “ets”.   |
| object | Object of class “ets”. Used for ggplot graphics (S3 method consistency). |
| ...    | Other plotting parameters to affect the plot.                            |

**Value**

None. Function produces a plot

**Author(s)**

Rob J Hyndman & Mitchell O’Hara-Wild

**See Also**[ets](#)**Examples**

```
fit <- ets(USAccDeaths)
plot(fit)
plot(fit, plot.type="single", ylab="", col=1:3)

library(ggplot2)
autoplot(fit)
```

plot.forecast

*Forecast plot***Description**

Plots historical data with forecasts and prediction intervals.  
 autoplot will produce an equivalent plot as a ggplot object.

**Usage**

```
## S3 method for class 'forecast'
plot(x, include, plot.conf=TRUE, shaded=TRUE,
     shadebars=(length(x$mean)<5), shadecols=NULL, col=1, fcol=4,
     pi.col=1, pi.lty=2, ylim=NULL, main=NULL, xlab="", ylab="", type="l",
     flty=1, flwd=2, ...)
## S3 method for class 'forecast'
autoplot(object, include, plot.conf=TRUE,
         shadecols=c("#596DD5", "#D5DBFF"), fcol="#0000AA", flwd=0.5, ...)
## S3 method for class 'splineforecast'
plot(x, fitcol=2, type="o", pch=19, ...)
## S3 method for class 'splineforecast'
autoplot(object, plot.conf=TRUE, ...)
```

**Arguments**

|           |  |
|-----------|--|
| x         | Forecast object produced by <a href="#">forecast</a> .   |
| object    | Forecast object produced by <a href="#">forecast</a> . Used for ggplot graphics (S3 method consistency). |
| include   | number of values from time series to include in plot. Default is all values.                             |
| plot.conf | Logical flag indicating whether to plot prediction intervals.  |
| shaded    | Logical flag indicating whether prediction intervals should be shaded (TRUE) or lines (FALSE)            |

|           |   |
|-----------|---|
| shadecols | Logical flag indicating if prediction intervals should be plotted as shaded bars (if TRUE) or a shaded polygon (if FALSE). Ignored if shaded=FALSE. Bars are plotted by default if there are fewer than five forecast horizons. |
| shadecols | Colors for shaded prediction intervals. To get default colors used prior to v3.26, set shadecols="oldstyle".  |
| col       | Colour for the data line.   |
| fcol      | Colour for the forecast line.   |
| flty      | Line type for the forecast line.  |
| flwd      | Line width for the forecast line.   |
| pi.col    | If shaded=FALSE and plot.conf=TRUE, the prediction intervals are plotted in this colour.  |
| pi.lty    | If shaded=FALSE and plot.conf=TRUE, the prediction intervals are plotted using this line type.  |
| ylim      | Limits on y-axis.   |
| main      | Main title.   |
| xlab      | X-axis label.   |
| ylab      | Y-axis label.   |
| fitcol    | Line colour for fitted values.  |
| type      | 1-character string giving the type of plot desired. As for <a href="#">plot.default</a> .   |
| pch       | Plotting character (if type=="p" or type=="o").   |
| ...       | Other plotting parameters to affect the plot.   |

**Value**

None.

plot.mforecast

*Multivariate forecast plot*

---

**Description**

Plots historical data with multivariate forecasts and prediction intervals.  
 autoplot will produce an equivalent plot as a ggplot object.

**Usage**

```

## S3 method for class 'mforecast'
plot(x, main=paste("Forecasts from",x$method),xlab="time",...)
## S3 method for class 'mforecast'
autoplot(object, plot.conf=TRUE, gridlayout=NULL, ...)

```

**Arguments**

|            |   |
|------------|---|
| x          | Multivariate forecast object of class mforecast.  |
| object     | Multivariate forecast object of class mforecast. Used for ggplot graphics (S3 method consistency).  |
| main       | Main title. Default is the forecast method. For autoplot, specify a vector of titles for each plot. |
| xlab       | X-axis label. For autoplot, specify a vector of labels for each plot.                               |
| plot.conf  | If FALSE, confidence intervals will not be plotted, giving only the forecast line.                  |
| gridlayout | A matrix of positions for the each forecast plot to be positioned.                                  |
| ...        | additional arguments to each individual plot.   |

**Examples**

```
plot(AirPassengers)
lines(seasadj(decompose(AirPassengers,"multiplicative")),col=4)
```

---

seasonaldummy

*Seasonal dummy variables*

---

**Description**

seasonaldummy returns matrices of dummy variables suitable for use in [arima](#), [lm](#) or [tslm](#). The last season is omitted and used as the control.

fourier returns matrices containing terms from a Fourier series, up to order K, suitable for use in [arima](#), [lm](#) or [tslm](#).

fourierf and seasonaldummyf are deprecated, instead use the h argument in fourier and seasonaldummy.

**Usage**

```
seasonaldummy(x,h)
fourier(x,K,h)
```

**Arguments**

|   |  |
|---|--|
| x | Seasonal time series: a ts or a msts object    |
| h | Number of periods ahead to forecast (optional) |
| K | Maximum order(s) of Fourier terms              |

**Details**

The number of dummy variables, or the period of the Fourier terms, is determined from the time series characteristics of x. The length of x also determines the number of rows for the matrices returned by seasonaldummy and fourier. The value of h determines the number of rows for the matrices returned by seasonaldummy and fourier, typically used for forecasting. The values within x are not used in any function.

When x is a ts object, the value of K should be an integer and specifies the number of sine and cosine terms to return. Thus, the matrix returned has 2\*K columns.

When x is a msts object, then K should be a vector of integers specifying the number of sine and cosine terms for each of the seasonal periods. Then the matrix returned will have 2\*sum(K) columns.

**Value**

Numerical matrix.

**Author(s)**

Rob J Hyndman

**Examples**

```

plot(ldeaths)

# Using seasonal dummy variables
month <- seasonaldummy(ldeaths)
deaths.lm <- tslm(ldeaths ~ month)
tsdisplay(residuals(deaths.lm))
ldeaths.fcast <- forecast(deaths.lm,
  data.frame(month=I(seasonaldummy(ldeaths,36))))
plot(ldeaths.fcast)

# A simpler approach to seasonal dummy variables
deaths.lm <- tslm(ldeaths ~ season)
ldeaths.fcast <- forecast(deaths.lm, h=36)
plot(ldeaths.fcast)

# Using Fourier series
deaths.lm <- tslm(ldeaths ~ fourier(ldeaths,3))
ldeaths.fcast <- forecast(deaths.lm,
  data.frame(fourier(ldeaths,3,36)))
plot(ldeaths.fcast)

# Using Fourier series for a "msts" object
taylor.lm <- tslm(taylor ~ fourier(taylor, K = c(3, 3)))
taylor.fcast <- forecast(taylor.lm,
  data.frame(fourier(taylor, K = c(3, 3), h = 270)))
plot(taylor.fcast)

```

---

seasonplot

*Seasonal plot*

---

**Description**

Plots a seasonal plot as described in Hyndman and Athanasopoulos (2014, chapter 2).

**Usage**

```

seasonplot(x, s, season.labels=NULL, year.labels=FALSE,
  year.labels.left=FALSE, type="o", main, xlab=NULL, ylab="",
  col=1, labelgap=0.1, ...)

ggseasonplot(x, year.labels=FALSE, year.labels.left=FALSE,
  type=NULL, col=NULL, continuous=FALSE, labelgap=0.04,
  ...)

```

**Arguments**

|                               |  |
|-------------------------------|--|
| <code>x</code>                | a numeric vector or time series.   |
| <code>s</code>                | seasonal frequency of <code>x</code>   |
| <code>season.labels</code>    | Labels for each season in the "year"   |
| <code>year.labels</code>      | Logical flag indicating whether labels for each year of data should be plotted on the right. |
| <code>year.labels.left</code> | Logical flag indicating whether labels for each year of data should be plotted on the left.  |
| <code>type</code>             | plot type (as for <code>plot</code> ). Not yet supported for <code>ggseasonplot</code> .     |
| <code>main</code>             | Main title.  |
| <code>xlab</code>             | X-axis label.  |
| <code>ylab</code>             | Y-axis label.  |
| <code>col</code>              | Colour   |
| <code>continuous</code>       | Should the colour scheme for years be continuous or discrete?                                |
| <code>labelgap</code>         | Distance between year labels and plotted lines   |
| <code>...</code>              | additional arguments to <code>plot</code> .  |

**Value**

None.

**Author(s)**

Rob J Hyndman & Mitchell O'Hara-Wild

```

---

ses *Exponential smoothing forecasts*

---

**Description**

Returns forecasts and other information for exponential smoothing forecasts applied to *y*.

**Usage**

```
ses(y, h=10, level=c(80,95), fan=FALSE,
    initial=c("optimal","simple"), alpha=NULL,
    lambda=NULL, biasadj=FALSE, x=y, ...)
holt(y, h=10, damped=FALSE, level=c(80,95), fan=FALSE,
    initial=c("optimal","simple"), exponential=FALSE,
    alpha=NULL, beta=NULL, lambda=NULL, biasadj=FALSE, x=y, ...)
hw(y, h=2*frequency(x), seasonal=c("additive","multiplicative"),
    damped=FALSE, level=c(80,95), fan=FALSE,
    initial=c("optimal","simple"), exponential=FALSE,
    alpha=NULL, beta=NULL, gamma=NULL,
    lambda=NULL, biasadj=FALSE, x=y, ...)
```

**Arguments**

|                    |  |
|--------------------|--|
| <i>y</i>           | a numeric vector or time series  |
| <i>h</i>           | Number of periods for forecasting.   |
| <i>damped</i>      | If TRUE, use a damped trend.   |
| <i>seasonal</i>    | Type of seasonality in hw model. "additive" or "multiplicative"  |
| <i>level</i>       | Confidence level for prediction intervals.   |
| <i>fan</i>         | If TRUE, level is set to seq(51,99,by=3). This is suitable for fan plots.  |
| <i>initial</i>     | Method used for selecting initial state values. If <i>optimal</i> , the initial values are optimized along with the smoothing parameters using <i>ets</i> . If <i>simple</i> , the initial values are set to values obtained using simple calculations on the first few observations. See Hyndman & Athanasopoulos (2014) for details. |
| <i>exponential</i> | If TRUE, an exponential trend is fitted. Otherwise, the trend is (locally) linear.   |
| <i>alpha</i>       | Value of smoothing parameter for the level. If NULL, it will be estimated.   |
| <i>beta</i>        | Value of smoothing parameter for the trend. If NULL, it will be estimated.   |
| <i>gamma</i>       | Value of smoothing parameter for the seasonal component. If NULL, it will be estimated.  |
| <i>lambda</i>      | Box-Cox transformation parameter. Ignored if NULL. Otherwise, data transformed before model is estimated. When <i>lambda</i> =TRUE, <i>additive.only</i> is set to FALSE.  |
| <i>biasadj</i>     | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities.  |

x                    Deprecated. Included for backwards compatibility.  
 ...                 Other arguments passed to `forecast.ets`.

### Details

`ses`, `holt` and `hw` are simply convenient wrapper functions for `forecast(ets(...))`.

### Value

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `ets` and associated functions.

An object of class "forecast" is a list containing at least the following elements:

|                        |   |
|------------------------|---|
| <code>model</code>     | A list containing information about the fitted model  |
| <code>method</code>    | The name of the forecasting method as a character string  |
| <code>mean</code>      | Point forecasts as a time series  |
| <code>lower</code>     | Lower limits for prediction intervals   |
| <code>upper</code>     | Upper limits for prediction intervals   |
| <code>level</code>     | The confidence values associated with the prediction intervals  |
| <code>x</code>         | The original time series (either object itself or the time series used to create the model stored as object). |
| <code>residuals</code> | Residuals from the fitted model. That is <code>x</code> minus fitted values.                                  |
| <code>fitted</code>    | Fitted values (one-step forecasts)  |

plot(deaths.fcast)
```

simulate.ets

*Simulation from a time series model***Description**

Returns a time series based on the model object object.

**Usage**

```
## S3 method for class 'ets'
simulate(object, nsim=length(object$x), seed=NULL, future=TRUE,
         bootstrap=FALSE, innov=NULL, ...)
## S3 method for class 'ar'
simulate(object, nsim=object$n.used, seed=NULL, future=TRUE,
         bootstrap=FALSE, innov=NULL, ...)
## S3 method for class 'Arima'
simulate(object, nsim=length(object$x), seed=NULL, xreg=NULL, future=TRUE,
         bootstrap=FALSE, innov=NULL, lambda=object$lambda, ...)
## S3 method for class 'fracdiff'
simulate(object, nsim=object$n, seed=NULL, future=TRUE,
         bootstrap=FALSE, innov=NULL, ...)
## S3 method for class 'nnetar'
simulate(object, nsim=length(object$x), seed=NULL, xreg=NULL, future=TRUE,
         bootstrap=FALSE, innov=NULL, lambda=object$lambda, ...)
```

**Arguments**

|           |  |
|-----------|--|
| object    | An object of class "ets", "Arima", "ar" or "nnetar".   |
| nsim      | Number of periods for the simulated series   |
| seed      | Either NULL or an integer that will be used in a call to <a href="#">set.seed</a> before simulating the time series. The default, NULL will not change the random generator state. |
| future    | Produce sample paths that are future to and conditional on the data in object.   |
| bootstrap | If TRUE, simulation uses resampled errors rather than normally distributed errors or errors provided as innov.   |
| innov     | A vector of innovations to use as the error series. Ignored if bootstrap==TRUE.  |
| xreg      | New values of xreg to be used for forecasting. Must have nsim rows.  |
| lambda    | Box-Cox parameter. If not NULL, the simulated series is transformed using an inverse Box-Cox transformation with parameter lamda.  |
| ...       | Other arguments.   |

### Details

With `simulate.Arima()`, the object should be produced by `Arima` or `auto.arima`, rather than `arima`. By default, the error series is assumed normally distributed and generated using `rnorm`. If `innov` is present, it is used instead. If `bootstrap=TRUE` and `innov=NULL`, the residuals are resampled instead.

When `future=TRUE`, the sample paths are conditional on the data. When `future=FALSE` and the model is stationary, the sample paths do not depend on the data at all. When `future=FALSE` and the model is non-stationary, the location of the sample paths is arbitrary, so they all start at the value of the first observation.

### Value

An object of class "ts".

### Author(s)

Rob J Hyndman

### See Also

### Examples

```
fit <- ets(USAccDeaths)
plot(USAccDeaths, xlim=c(1973, 1982))
lines(simulate(fit, 36), col="red")
```

---

sindexf

*Forecast seasonal index*

---

### Description

Returns vector containing the seasonal index for `h` future periods. If the seasonal index is non-periodic, it uses the last values of the index.

### Usage

```
sindexf(object, h)
```

### Arguments

`object` Output from [decompose](#) or [stl](#).  
`h` Number of periods ahead to forecast

### Value

Time series

**Author(s)**

Rob J Hyndman

**Examples**

```
uk.stl <- stl(UKDriverDeaths,"periodic")
uk.sa <- seasadj(uk.stl)
uk.fcast <- holt(uk.sa,36)
seasf <- sindexf(uk.stl,36)
uk.fcast$mean <- uk.fcast$mean + seasf
uk.fcast$lower <- uk.fcast$lower + cbind(seasf,seasf)
uk.fcast$upper <- uk.fcast$upper + cbind(seasf,seasf)
uk.fcast$x <- UKDriverDeaths
plot(uk.fcast,main="Forecasts from Holt's method with seasonal adjustment")
```

splinef

*Cubic Spline Forecast***Description**

Returns local linear forecasts and prediction intervals using cubic smoothing splines.

**Usage**

```
splinef(y, h=10, level=c(80,95), fan=FALSE, lambda=NULL, biasadj=FALSE,
        method=c("gcv","mle"), x=y)
```

**Arguments**

|         |  |
|---------|--|
| y       | a numeric vector or time series  |
| h       | Number of periods for forecasting  |
| level   | Confidence level for prediction intervals.   |
| fan     | If TRUE, level is set to seq(51,99,by=3). This is suitable for fan plots.  |
| lambda  | Box-Cox transformation parameter. Ignored if NULL. Otherwise, forecasts back-transformed via an inverse Box-Cox transformation.  |
| biasadj | Use adjusted back-transformed mean for Box-Cox transformations. If TRUE, point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities.                        |
| method  | Method for selecting the smoothing parameter. If method="gcv", the generalized cross-validation method from <a href="#">smooth.spline</a> is used. If method="mle", the maximum likelihood method from Hyndman et al (2002) is used. |
| x       | Deprecated. Included for backwards compatibility.  |

**Details**

The cubic smoothing spline model is equivalent to an ARIMA(0,2,2) model but with a restricted parameter space. The advantage of the spline model over the full ARIMA model is that it provides a smooth historical trend as well as a linear forecast function. Hyndman, King, Pitrun, and Billah (2002) show that the forecast performance of the method is hardly affected by the restricted parameter space.

**Value**

An object of class "forecast".

The function `summary` is used to obtain and print a summary of the results, while the function `plot` produces a plot of the forecasts and prediction intervals.

The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `splinef`.

An object of class "forecast" containing the following elements:

|                        |   |
|------------------------|---|
| <code>model</code>     | A list containing information about the fitted model  |
| <code>method</code>    | The name of the forecasting method as a character string  |
| <code>mean</code>      | Point forecasts as a time series  |
| <code>lower</code>     | Lower limits for prediction intervals   |
| <code>upper</code>     | Upper limits for prediction intervals   |
| <code>level</code>     | The confidence values associated with the prediction intervals  |
| <code>x</code>         | The original time series (either object itself or the time series used to create the model stored as object). |
| <code>onestepf</code>  | One-step forecasts from the fitted model.   |
| <code>fitted</code>    | Smooth estimates of the fitted trend using all data.  |
| <code>residuals</code> | Residuals from the fitted model. That is <code>x</code> minus one-step forecasts.                             |

subset.ts                      *Subsetting a time series*

---

### Description

Extracts the values of a specific season or subset of seasons in each year. For example, to extract all values for the month of May from a time series.

### Usage

```
## S3 method for class 'ts'  
subset(x, subset=NULL, month=NULL, quarter=NULL, season=NULL, ...)
```

### Arguments

|         |  |
|---------|--|
| x       | a univariate time series to be subsetted   |
| subset  | optional logical expression indicating elements to keep; missing values are taken as false. subset must be the same length as x. |
| month   | Numeric or character vector of months to retain. Partial matching on month names used.   |
| quarter | Numeric or character vector of quarters to retain.   |
| season  | Numeric vector of seasons to retain.   |
| ...     | Other arguments, unused.   |

### Details

If character values for months are used, either upper or lower case may be used, and partial unambiguous names are acceptable. Possible character values for quarters are "Q1", "Q2", "Q3", and "Q4".

### Value

If subset is used, a numeric vector is returned with no ts attributes. Otherwise, a ts object is returned with frequency equal to the length of month, quarter or season.

```

---

|       |  |
|-------|--|
| tbats | <i>TBATS model (Exponential smoothing state space model with Box-Cox transformation, ARMA errors, Trend and Seasonal components)</i> |
|-------|--|

---

**Description**

Fits a TBATS model applied to  $y$ , as described in De Livera, Hyndman & Snyder (2011). Parallel processing is used by default to speed up the computations.

**Usage**

```
tbats(y, use.box.cox=NULL, use.trend=NULL, use.damped.trend=NULL,
      seasonal.periods=NULL, use.arma.errors=TRUE, use.parallel=length(y)>1000,
      num.cores=2, bc.lower=0, bc.upper=1, model=NULL, ...)
```

**Arguments**

|                               |   |
|-------------------------------|---|
| <code>y</code>                | The time series to be forecast. Can be numeric, <code>msts</code> or <code>ts</code> . Only univariate time series are supported.   |
| <code>use.box.cox</code>      | TRUE/FALSE indicates whether to use the Box-Cox transformation or not. If NULL then both are tried and the best fit is selected by AIC.   |
| <code>use.trend</code>        | TRUE/FALSE indicates whether to include a trend or not. If NULL then both are tried and the best fit is selected by AIC.  |
| <code>use.damped.trend</code> | TRUE/FALSE indicates whether to include a damping parameter in the trend or not. If NULL then both are tried and the best fit is selected by AIC.   |
| <code>seasonal.periods</code> | If <code>y</code> is numeric then seasonal periods can be specified with this parameter.  |
| <code>use.arma.errors</code>  | TRUE/FALSE indicates whether to include ARMA errors or not. If TRUE the best fit is selected by AIC. If FALSE then the selection algorithm does not consider ARMA errors.   |
| <code>use.parallel</code>     | TRUE/FALSE indicates whether or not to use parallel processing.   |
| <code>num.cores</code>        | The number of parallel processes to be used if using parallel processing. If NULL then the number of logical cores is detected and all available cores are used.  |
| <code>bc.lower</code>         | The lower limit (inclusive) for the Box-Cox transformation.   |
| <code>bc.upper</code>         | The upper limit (inclusive) for the Box-Cox transformation.   |
| <code>model</code>            | Output from a previous call to <code>tbats</code> . If <code>model</code> is passed, this same model is fitted to <code>y</code> without re-estimating any parameters.  |
| <code>...</code>              | Additional arguments to be passed to <code>auto.arima</code> when choose an ARMA( $p$ , $q$ ) model for the errors. (Note that <code>xreg</code> will be ignored, as will any arguments concerning seasonality and differencing, but arguments controlling the values of $p$ and $q$ will be used.) |

**Value**

An object with class `c("tbats", "bats")`. The generic accessor functions `fitted.values` and `residuals` extract useful features of the value returned by `bats` and associated functions. The fitted model is designated TBATS( $\omega$ ,  $p$ ,  $q$ ,  $\phi$ ,  $\langle m_1, k_1 \rangle, \dots, \langle m_J, k_J \rangle$ ) where  $\omega$  is the Box-Cox parameter and  $\phi$  is the damping parameter; the error is modelled as an ARMA( $p$ ,  $q$ ) process and  $m_1, \dots, m_J$  list the seasonal periods used in the model and  $k_1, \dots, k_J$  are the corresponding number of Fourier terms used for each seasonality.

```

---

|        |                              |
|--------|------------------------------|
| thetaf | <i>Theta method forecast</i> |
|--------|------------------------------|

---

**Description**

Returns forecasts and prediction intervals for a theta method forecast.

**Usage**

```
thetaf(y, h=ifelse(frequency(y)>1, 2*frequency(y), 10),
       level=c(80,95), fan=FALSE, x=y)
```

**Arguments**

|       |   |
|-------|---|
| y     | a numeric vector or time series   |
| h     | Number of periods for forecasting   |
| level | Confidence levels for prediction intervals.                               |
| fan   | If TRUE, level is set to seq(51,99,by=3). This is suitable for fan plots. |
| x     | Deprecated. Included for backwards compatibility.                         |

**Details**

The theta method of Assimakopoulos and Nikolopoulos (2000) is equivalent to simple exponential smoothing with drift. This is demonstrated in Hyndman and Billah (2003).

The series is tested for seasonality using the test outlined in A&N. If deemed seasonal, the series is seasonally adjusted using a classical multiplicative decomposition before applying the theta method. The resulting forecasts are then reseasonalized.

Prediction intervals are computed using the underlying state space model.

More general theta methods are available in the [forecTheta](#) package.

**Value**

An object of class "forecast".

The function summary is used to obtain and print a summary of the results, while the function plot produces a plot of the forecasts and prediction intervals.

The generic accessor functions fitted.values and residuals extract useful features of the value returned by rwf.

An object of class "forecast" is a list containing at least the following elements:

|           |   |
|-----------|---|
| model     | A list containing information about the fitted model  |
| method    | The name of the forecasting method as a character string  |
| mean      | Point forecasts as a time series  |
| lower     | Lower limits for prediction intervals   |
| upper     | Upper limits for prediction intervals   |
| level     | The confidence values associated with the prediction intervals  |
| x         | The original time series (either object itself or the time series used to create the model stored as object). |
| residuals | Residuals from the fitted model. That is x minus fitted values.   |
| fitted    | Fitted values (one-step forecasts)  |

tsclean

*Identify and replace outliers and missing values in a time series*

---

**Description**

Uses supsmu for non-seasonal series and a periodic stl decomposition with seasonal series to identify outliers. To estimate missing values and outlier replacements, linear interpolation is used on the (possibly seasonally adjusted) series

**Usage**

```
tsclean(x, replace.missing = TRUE, lambda = NULL)
```

**Arguments**

`x` time series  
`replace.missing` If TRUE, it not only replaces outliers, but also interpolates missing values  
`lambda` a numeric value giving the Box-Cox transformation parameter

**Value**

Time series

**Author(s)**

|           |                            |
|-----------|----------------------------|
| tsdisplay | <i>Time series display</i> |
|-----------|----------------------------|

---

**Description**

Plots a time series along with its acf and either its pacf, lagged scatterplot or spectrum.

`ggtsdisplay` will produce the equivalent plot using `ggplot` graphics.

**Usage**

```
tsdisplay(x, plot.type=c("partial","scatter","spectrum"),
  points=TRUE, ci.type=c("white", "ma"),
  lag.max, na.action=na.contiguous,
  main=NULL, xlab="", ylab="", pch=1, cex=0.5, ...)

ggtsdisplay(x, plot.type=c("partial","scatter","spectrum"),
  points=TRUE, lag.max, na.action=na.contiguous, theme=NULL, ...)
```

**Arguments**

|                        |  |
|------------------------|--|
| <code>x</code>         | a numeric vector or time series.   |
| <code>plot.type</code> | type of plot to include in lower right corner.   |
| <code>points</code>    | logical flag indicating whether to show the individual points or not in the time plot.   |
| <code>ci.type</code>   | type of confidence limits for ACF that is passed to <code>acf</code> . Should the confidence limits assume a white noise input or for lag $k$ an $MA(k - 1)$ input?  |
| <code>lag.max</code>   | the maximum lag to plot for the <code>acf</code> and <code>pacf</code> . A suitable value is selected by default if the argument is missing.   |
| <code>na.action</code> | function to handle missing values in <code>acf</code> , <code>pacf</code> and spectrum calculations. The default is <code>na.contiguous</code> . Useful alternatives are <code>na.pass</code> and <code>na.interp</code> . |
| <code>theme</code>     | Adds a <code>ggplot</code> element to each plot, typically a theme.  |
| <code>main</code>      | Main title.  |
| <code>xlab</code>      | X-axis label.  |
| <code>ylab</code>      | Y-axis label.  |
| <code>pch</code>       | Plotting character.  |
| <code>cex</code>       | Character size.  |
| <code>...</code>       | additional arguments to <code>acf</code> .   |

**Value**

None.

```

---

`tslm`*Fit a linear model with time series components*

---

### Description

`tslm` is used to fit linear models to time series including trend and seasonality components.

### Usage

```
tslm(formula, data, subset, lambda=NULL, biasadj=FALSE, ...)
```

### Arguments

|                      |   |
|----------------------|---|
| <code>formula</code> | an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted.  |
| <code>data</code>    | an optional data frame, list or environment (or object coercible by <code>as.data.frame</code> to a data frame) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>lm</code> is called. |
| <code>subset</code>  | an optional subset containing rows of data to keep. For best results, pass a logical vector of rows to keep. Also supports <code>subset()</code> functions.   |
| <code>lambda</code>  | Box-Cox transformation parameter. Ignored if <code>NULL</code> . Otherwise, data are transformed via a Box-Cox transformation.  |
| <code>biasadj</code> | Use adjusted back-transformed mean for Box-Cox transformations. If <code>TRUE</code> , point forecasts and fitted values are mean forecast. Otherwise, these points can be considered the median of the forecast densities.   |
| <code>...</code>     | Other arguments passed to <code>lm()</code> .   |

### Details

`tslm` is largely a wrapper for `lm()` except that it allows variables "trend" and "season" which are created on the fly from the time series characteristics of the data. The variable "trend" is a simple time trend and "season" is a factor indicating the season (e.g., the month or the quarter depending on the frequency of the data).

### Value

Returns an object of class "lm".

### Author(s)

Mitchell O'Hara-Wild and Rob J Hyndman

### See Also

**Examples**

```
y <- ts(rnorm(120,0,3) + 1:120 + 20*sin(2*pi*(1:120)/12), frequency=12)
fit <- tslm(y ~ trend + season)
plot(forecast(fit, h=20))
```

---

**tsoutliers***Identify and replace outliers in a time series*

---

**Description**

Uses supsmu for non-seasonal series and a periodic stl decomposition with seasonal series to identify outliers and estimate their replacements.

**Usage**

```
tsoutliers(x, iterate = 2, lambda = NULL)
```

**Arguments**

|         |  |
|---------|--|
| x       | time series  |
| iterate | the number of iteration only for non-seasonal series |
| lambda  | Allowing Box-cox transformation                      |

**Value**

|             |   |
|-------------|---|
| index       | Indicating the index of outlier(s)                      |
| replacement | Suggested numeric values to replace identified outliers |

**Author(s)**

Rob J Hyndman

|          |  |
|----------|--|
| woolyrnq | <i>Quarterly production of woollen yarn in Australia</i> |
|----------|--|

---

**Description**

Quarterly production of woollen yarn in Australia: tonnes. Mar 1965 – Sep 1994.

**Usage**

```
woolyrnq
```

**Format**

Time series data

**Source**

Time Series Data Library. <http://data.is/TSDLdemo>

**Examples**

```
tsdisplay(woolyrnq)
```
