

# Package ‘GAparsimony’

August 4, 2017

**Type** Package

**Title** Searching Parsimony Models with Genetic Algorithms

**Version** 0.9-1

**Date** 2017-07-31

**Description** Methodology that combines feature selection, model tuning, and parsimonious model selection with Genetic Algorithms (GA) proposed in {Martinez-de-Pison} (2015) <DOI:10.1016/j.asoc.2015.06.012>. To this objective, a novel GA selection procedure is introduced based on separate cost and complexity evaluations.

**Suggests** parallel, doParallel, doRNG (>= 1.6), knitr (>= 1.8), lhs, MASS, caret, mlbench, e1071, nnet, kernlab

**License** GPL (>= 2)

**Depends** R (>= 3.0), methods, foreach, iterators

**Imports** stats, graphics, grDevices, utils

**URL** <https://github.com/jpison/GAparsimony>

**Repository** CRAN

**NeedsCompilation** no

**Author** F.J. Martinez-de-Pison [aut, cre]

**Maintainer** F.J. Martinez-de-Pison <fjmartin@unirioja.es>

**Date/Publication** 2017-08-03 22:53:42 UTC

GAparsimony-package      *GAparsimony*

---

## Description

Combines feature selection, model tuning, and parsimonious model selection with GA optimization. GA selection procedure is based on separate cost and complexity evaluations. Therefore, the best individuals are initially sorted by an error fitness function, and afterwards, models with similar costs are rearranged according to model complexity measurement so as to foster models of lesser complexity. The algorithm can be run sequentially or in parallel using an explicit master-slave parallelisation.

## Details

**GAparsimony** package is a new GA wrapper automatic method that efficiently generated prediction models with reduced complexity and adequate generalization capacity. `ga_parsimony` function is primarily based on combining feature selection and model parameter tuning with a second novel GA selection process (ReRank algorithm) in order to achieve better overall parsimonious models. Unlike other GA methodologies that use a penalty parameter for combining loss and complexity measures into a unique fitness function, the main contribution of this package is that `ga_parsimony` selects the best models by considering cost and complexity separately. For this purpose, the ReRank algorithm rearranges individuals by their complexity when there is not a significant difference between their costs. Thus, less complex models with similar accuracy are promoted. Furthermore, because the penalty parameter is unnecessary, there is no consequent uncertainty associated with assigning a correct value beforehand. As a result, with GA-PARSIMONY, an automatic method for obtaining parsimonious models is finally made possible.

 ga\_parsimony

 GA-PARSIMONY
 

---

**Description**

A GA-based optimization method for searching accurate parsimonious models by combining feature selection, model tuning, and parsimonious model selection (PMS). PMS procedure is based on separate cost and complexity evaluations. The best individuals are initially sorted by an error fitness function, and afterwards, models with similar costs are rearranged according to model complexity measurement so as to foster models of lesser complexity. The algorithm can be run sequentially or in parallel using an explicit master-slave parallelisation.

**Usage**

```
ga_parsimony(fitness, ...,
  min_param, max_param, nFeatures,
  names_param=NULL, names_features=NULL,
  iter_ini=0, object=NULL,
  type_ini_pop="improvedLHS",
  popSize = 50, pcrossover = 0.8, maxiter = 40,
  feat_thres=0.90, rerank_error = 0.0, iter_start_rerank = 0,
  pmutation = 0.10, feat_mut_thres=0.10, not_muted=3,
  elitism = base::max(1, round(popSize * 0.20)),
  population = parsimony_population,
  selection = parsimony_nlrSelection,
  crossover = parsimony_crossover,
  mutation = parsimony_mutation,
  keep_history = FALSE,
  early_stop = maxiter, maxFitness = Inf, suggestions = NULL,
  parallel = FALSE,
  monitor = if (interactive()) parsimony_monitor else FALSE,
  seed_ini = NULL, verbose=FALSE)
```

**Arguments**

fitness	the fitness function, any allowable R function which takes as input an individual chromosome which combines the model parameters to tune and the features to be selected. Fitness function returns a numerical vector with three values: "validation_cost": a robust validation cost measure, J (RMSE, AUC, Logloss). For example, n-repeated cross validation (CV) RMSE for regression or n-repeated CV Logloss or AUC for classification; "testing_cost": testing cost obtained with a testing dataset not included in the validation process. This value is only for checking the generalization capability of the model. NA value can be supplied if there is not a testing data set; "model_complexity": model
---------	---

complexity. Can be the number of features, number of support vectors in SVM, sum of power of weights in ANNs, depth in Trees, generalised degrees of freedom (GDF), or another complexity metrics o combination of them.

Note: the chromosome is a concatenated real vector with the model parameters (parameters-chromosome) and the binary selection of the input features (features-chromosome). For example, a chromosome defined as  $c(10, 0.01, 0, 1, 1, 0, 1, 0, 0)$  could corresponds to a SVR model parameters  $C=10$  &  $\gamma=0.01$ , and a selection of three input features (second, third and fifth) from a dataset of 7 features (0110100).

...	additional arguments to be passed to the fitness function. This allows to write fitness functions that keep some variables fixed during the search.
min_param	a vector of length equal to the model parameters providing the minimum of the search space.
max_param	a vector of length equal to the model parameters providing the maximum of the search space.
nFeatures	a value specifying the number of maximum input features.
names_param	a vector with the name of the model parameters.
names_features	a vector with the name of the input features.
iter_ini	initial iteration. If 'iter_ini' is > 0, 'object' must be provided to continue the optimization process.
object	object of 'ga_parsimony' class to use if 'iter_ini'>0
type_ini_pop	method to create the first population with 'parsimony_population' function. This function is called when iter_ini==0 and 'suggestions' are not provided. Methods='randomLHS', 'geneticLHS', 'improvedLHS', 'maximinLHS', 'optimumLHS', 'random'. First 5 methods correspond with several latine hypercube sampling.
popSize	the population size.
pcrossover	the probability of crossover between pairs of chromosomes. Typically this is a large value and by default is set to 0.8.
maxiter	the maximum number of iterations to run before the GA process is halted.
feat_thres	proportion of selected features in the initial population. It is recommended a high percentage of selected features for the first generations. By default is set to 0.90.
rerank_error	when a value is provided, a second reranking process according to the model complexities is called by <a href="#">parsimony_rerank</a> function. Its primary objective is to select individuals with high validation cost while maintaining the robustness of a parsimonious model. This function switches the position of two models if the first one is more complex than the latter and no significant difference is found between their fitness values in terms of cost. Therefore, if the absolute difference between the validation costs are lower than 'rerank_error' they are considered similar. Default value=0.01
iter_start_rerank	iteration when ReRanking process is activated. Default=0. Sometimes is useful not to use ReRanking process in the first generations.

pmutation	the probability of mutation in a parent chromosome. Usually mutation occurs with a small probability. By default is set to 0.10.
feat_mut_thres	probability of the muted 'features-chromosome' to be one. Default value is set to 0.10.
not_muted	number of the best elitists that are not muted in each generation. Default value is set to 3.
elitism	the number of best individuals to survive at each generation. By default the top 20% individuals will survive at each iteration.
population	an R function for randomly generating an initial population. See <a href="#">parsimony_population</a> for available functions.
selection	an R function performing selection, i.e. a function which generates a new population of individuals from the current population probabilistically according to individual fitness. See <a href="#">parsimony_nlrSelection</a> for available functions.
crossover	an R function performing crossover, i.e. a function which forms offsprings by combining part of the genetic information from their parents. See <a href="#">parsimony_crossover</a> for available functions.
mutation	an R function performing mutation, i.e. a function which randomly alters the values of some genes in a parent chromosome. See <a href="#">parsimony_mutation</a> for available functions.
keep_history	If it is TRUE keeps in the list <code>object@history</code> each generation. This parameter must set TRUE in order to use 'plot' method or 'parsimony_importance' function.
early_stop	the number of consecutive generations without any improvement in the best fitness value before the GA is stopped.
maxFitness	the upper bound on the fitness function after that the GA search is interrupted. Default value is set to +Inf
suggestions	a matrix of solutions strings to be included in the initial population. If provided the number of columns must match ( <code>object@nParams+object@nFeatures</code> )
parallel	a logical argument specifying if parallel computing should be used (TRUE) or not (FALSE, default) for evaluating the fitness function. This argument could also be used to specify the number of cores to employ; by default, this is taken from <a href="#">detectCores</a> . Finally, the functionality of parallelization depends on system OS: on Windows only 'snow' type functionality is available, while on Unix/Linux/Mac OSX both 'snow' and 'multicore' (default) functionalities are available.
monitor	a logical or an R function which takes as input the current state of the <code>ga_parsimony</code> -class object and show the evolution of the search. By default, for interactive sessions, the function <a href="#">parsimony_monitor</a> depending on whether or not is an RStudio session, prints the average and best fitness values at each iteration. If set to <code>plot</code> these information are plotted on a graphical device. Other functions can be written by the user and supplied as argument. In non interactive sessions, by default <code>monitor = FALSE</code> so any output is suppressed.
seed_ini	an integer value containing the random number generator state. This argument can be used to replicate the results of a GA search. Note that if parallel computing is required, the <b>doRNG</b> package must be installed.
verbose	if it is TRUE shows additional information for debugging.

## Details

**GAparsimony** package is a new GA wrapper automatic procedure that efficiently generated prediction models with reduced complexity and adequate generalization capacity. `ga_parsimony` function is primarily based on combining feature selection and model parameter tuning with a second novel GA selection process (`parsimony_rerank` function), in order to achieve better overall parsimonious models. Unlike other GA methodologies that use a penalty parameter for combining loss and complexity measures into a unique fitness function, the main contribution of this package is that `ga_parsimony` selects the best models by considering cost and complexity separately. For this purpose, the ReRank algorithm rearranges individuals by their complexity when there is not a significant difference between their costs. Thus, less complex models with similar accuracy are promoted. Furthermore, because the penalty parameter is unnecessary, there is no consequent uncertainty associated with assigning a correct value beforehand. As a result, with GA-PARSIMONY, an automatic method for obtaining parsimonious models is finally made possible.

## Value

Returns an object of class `ga_parsimony-class`. See `ga_parsimony-class` for a description of available slots information.

---

ga\_parsimony-class      *Class "ga\_parsimony"*

---

### Description

An S4 class for searching parsimonious models by feature selection and parameter tuning with genetic algorithms.

### Objects from the Class

Objects can be created by calls to the [ga\\_parsimony](#) function.

### Slots

`call` an object of class "call" representing the matched call;  
`min_param` a vector of length equal to the model parameters providing the minimum of the search space;

**max\_param** a vector of length equal to the model parameters providing the maximum of the search space;  
**nParams** a value specifying the number of model parameter to be tuned;  
**feat\_thres** proportion of selected features in the initial population. It is recommended a high percentage of selected features for the first generations;  
**feat\_mut\_thres** threshold to consider a random number between 0 and 1 is considered one if a value of the parameters-chromosome is muted. Default value is set to 0.5;  
**not\_muted** number of the best elitists that are not muted. Default value is set to 3;  
**rerank\_error** when a value distinct to zero is provided a second reranking process according to the model complexities is called by 'parsimonyReRank' function. Its primary objective is to select individuals with high validation cost while maintaining the robustness of a parsimonious model. This function switches the position of two models if the first one is more complex than the latter and no significant difference is found between their fitness values in terms of cost. Therefore, if the absolute difference between the validation costs are lower than 'rerank\_error' they are considered similar. Default value=0.01;  
**nFeatures** a value specifying the number of maximum input features;  
**names\_param** a vector with the name of the model parameters;  
**names\_features** a vector with the name of the input features;  
**popSize** the population size;  
**iter** the actual (or final) iteration of GA search;  
**iter\_start\_rerank** iteration when ReRanking process is activated. Default=0. Sometimes is useful not to use ReRanking process in the first generations;  
**early\_stop** the number of consecutive generations without any improvement in the best fitness value before the GA is stopped;  
**maxiter** the maximum number of iterations to run before the GA search is halted;  
**minutes\_gen** elapsed time of this generation (in minutes);  
**minutes\_total** total elapsed time (in minutes);  
**suggestions** a matrix of user provided solutions and included in the initial population;  
**population** the current (or final) population;  
**elitism** the number of best fitness individuals to survive at each generation;  
**pcrossover** the crossover probability;  
**pmutation** the mutation probability;  
**fitnessval** the values of validation cost for the current (or final) population;  
**fitnessst** the values of testing cost for the current (or final) population;  
**complexity** the values of model complexities for the current (or final) population;  
**summary** a matrix of summary statistics for fitness values at each iteration (along the rows);  
**bestSolList** a list with the best solution of all iterations;  
**bestfitnessVal** the validation cost of the best solution at the last iteration;  
**bestfitnessTst** the testing cost of the best solution at the last iteration;  
**bestcomplexity** the model complexity of the best solution at the last iteration;  
**bestsolution** the best solution at the last iteration;  
**history** a list with the population of all iterations;

---

numericOrNA-class	<i>Virtual Class "numericOrNA" - Simple Class for subassignment Values</i>
-------------------	--

---

**Description**

The class "numericOrNA" is a simple class union ([setClassUnion](#)) of "numeric" and "logical".

**Objects from the Class**

Since it is a virtual Class, no objects may be created from it.

**Examples**

```
showClass("numericOrNA")
```

---

parsimony_crossover	<i>Crossover operators in GA-PARSIMONY</i>
---------------------	--

---

**Description**

Functions implementing particular crossover genetic operator for GA-PARSIMONY. Method uses for model parameters Heuristic Blending and random swapping for binary selected features.

**Usage**

```
parsimony_crossover(object, parents, alpha=0.1, perc_to_swap=0.5, ...)
```

**Arguments**

object	An object of class "ga_parsimony", usually resulting from a call to function <a href="#">ga_parsimony</a> .
parents	A two-rows matrix of values indexing the parents from the current population.
alpha	A tuning parameter for the Heuristic Blending outer bounds [Michalewicz, 1991]. Typical and default value is 0.1.
perc_to_swap	Percentage of features for swapping in the crossovering process.
...	Further arguments passed to or from other methods.

**Value**

Return a list with two elements:

children	Matrix of dimension 2 times the number of decision variables containing the generated offsprings;
fitnessval	Vector of length 2 containing the fitness validation values for the offsprings. A value NA is returned if an offspring is different (which is usually the case) from the two parents.
fitnessst	Vector of length 2 containing the fitness with the test database (if it was supplied), for the offsprings. A value NA is returned if an offspring is different (which is usually the case) from the two parents.
complexity	Vector of length 2 containing the model complexity for the offsprings. A value NA is returned if an offspring is different (which is usually the case) from the two parents.

---

parsimony\_importance *Percentage of appearance of each feature in elitist population*

---

**Description**

Shows the percentage of appearance of each feature in the whole GA-PARSIMONY process but only for the elitist-population.

**Usage**

```
parsimony_importance(object, verbose=FALSE, ...)
```

**Arguments**

object	An object of class "ga_parsimony" resulting from a call to function <a href="#">ga_parsimony</a> with keep_history parameter set to TRUE.
verbose	If it is TRUE shows additional information.
...	Further arguments passed to or from other methods.

**Details**

parsimony\_importance extracts elitist population from all generations. Obtains the percentage of appearance of each feature in the all GA process. Return the features higher-ordered.

**Value**

Return a vector with the higher-ordered percentage of appearance of each feature in the elitist-population and in the whole GA process.

---

parsimony\_monitor      *Functions for monitoring GA-PARSIMONY algorithm evolution*

---

**Description**

Functions to print summary statistics of fitness values at each iteration of a GA search.

**Usage**

```
parsimony_monitor(object, digits = getOption("digits"), ...)
```

**Arguments**

object	An object of class "ga_parsimony", usually resulting from a call to function <a href="#">ga_parsimony</a> .
digits	minimal number of significant digits.
...	Further arguments passed to or from other methods.

**Value**

These functions print a summary of current GA-PARSIMONY step on the console.

**Author(s)**

Francisco Javier Martinez de Pison. <fjmartin@unirioja.es>. EDMANS Group. <http://www.mineriadatos.com>

---

parsimony\_Mutation      *Mutation operators in GA-PARSIMONY*

---

### Description

Functions implementing mutation genetic operator for GA-PARSIMONY. Method mutes a `object@pmutation` percentage of them. If the value corresponds to a model parameter, algorithm uses uniform random mutation. For binary select features, method sets to one if the random value between [0,1] is lower or equal to `object@feat_mut_thres`.

### Usage

```
parsimony_mutation(object, ...)
```

### Arguments

`object`            An object of class "ga\_parsimony", usually resulting from a call to function [ga\\_parsimony](#).

`...`              Further arguments passed to or from other methods.

### Value

Return object with the population muted.

### Author(s)

Francisco Javier Martinez de Pison. <fjmartin@unirioja.es>. EDMANS Group. <http://www.mineriadatos.com>

[ga\\_parsimony](#)

---

parsimony\_Population      *Population initialization in GA-PARSIMONY with a combined chromosome of model parameters and selected features*

---

### Description

Functions for creating an initial population to be used in the GA-PARSIMONY process.

### Usage

```
parsimony_population(object, type_ini_pop="randomLHS", ...)
```

**Arguments**

object	An object of class "ga_parsimony", usually resulting from a call to function <a href="#">ga_parsimony</a> .
type_ini_pop	How to create the initial population. 'random' option initialize a random population between the predefined ranges. Values 'randomLHS', 'geneticLHS', 'improvedLHS', 'maximinLHS' & 'optimumLHS' corresponds with several methods of the Latin Hypercube Sampling (see 'lhs' package for more details).
...	Further arguments passed to or from other methods.

**Details**

`parsimony_population` generates a random population of `object@popSize` individuals. For each individual a random chromosome is generated with `object@nParams` real values in the range `[object@min_param, object@max_param]` plus `object@nFeatures` random binary values for feature selection. 'random' or Latin Hypercube Sampling can be used to create a efficient spread initial population.

**Value**

Return a matrix of dimension `object@popSize` rows and `object@nParams+object@nFeatures` columns.

<code>parsimony_rerank</code>	<i>Function for reranking by complexity in parsimonious model selection process</i>
-------------------------------	---

---

**Description**

Promotes models with similar fitness but lower complexity to top positions.

**Usage**

```
parsimony_rerank(object, verbose=FALSE, ...)
```

**Arguments**

object	An object of class "ga_parsimony" resulting from a call to function <code>ga_parsimony</code> with <code>keep_history</code> parameter set to TRUE.
verbose	If it is TRUE shows additional information.
...	Further arguments passed to or from other methods.

**Details**

This method corresponds with the second step of parsimonious model selection (PMS) procedure. PMS works in the following way: in each GA generation, best solutions are first sorted by their cost, J. Then, in a second step, individuals with less complexity are moved to the top positions when the absolute difference of their J is lower than a `object@rerank_error` threshold value. Therefore, the selection of less complex solutions among those with similar accuracy promotes the evolution of robust solutions with better generalization capabilities.

**Value**

Return a vector with the new position of the individuals.

**Author(s)**

Francisco Javier Martinez de Pison. <fjmartin@unirioja.es>. EDMANS Group. <http://www.mineriadatos.com>

**Examples**

```
library(GAparsimony)
object <- new("ga_parsimony",
             rerank_error=0.2,
             popSize = 4,
             fitnessval = c(2.0, 1.9, 1.1, 1.0),
             complexity=c(2,1,2,1))

pop_ini <- data.frame(fitnessval=object@fitnessval,
                    complexity=object@complexity)
print("INITIAL POPULATION:")
print(pop_ini)

print("POPULATION ORDERED BY COMPLEXITY")
print(paste0("WHEN abs(diff(fitnessval)) < ",
            object@rerank_error,":"))
pop_ini[parsimony_rerank(object),]
```

---

parsimony\_Selection     *Selection operators in GA-PARSIMONY*

---

### Description

Functions implementing selection genetic operator in GA-PARSIMONY after [parsimony\\_rerank](#) process. Linear-rank or Nonlinear-rank selection (Michalewicz (1996)).

### Usage

```
parsimony_lrSelection(object, r = 2/(object@popSize*(object@popSize-1)),
q = 2/object@popSize, ...)
parsimony_nlrSelection(object, q = 0.25, ...)
```

### Arguments

object	An object of class "ga_parsimony", usually resulting from a call to function <a href="#">ga_parsimony</a> .
r	A tuning parameter for the specific selection operator.
q	A tuning parameter for the specific selection operator.
...	Further arguments passed to or from other methods.

### Value

Return a list with four elements:

population	a matrix of dimension object@popSize times the number of decision variables containing the selected individuals or strings;
fitnessval	a vector of length object@popSize containing the fitness validation values for the selected individuals;
fitnessstt	a vector of length object@popSize containing the fitness with the test database (if it was supplied), for the selected individuals;
complexity	a vector of length object@popSize containing the model complexity for the selected individuals.

```
plot.ga_parsimony-method
```

*Plot of GA evolution of elitists*

---

### Description

The plot method for `ga_parsimony-class` objects gives a evolution plot of the validation and testing errors, and the number of model features selected of elitists.

### Usage

```
## S4 method for signature 'ga_parsimony'
plot(x, general_cex = 0.7, min_ylim=NULL, max_ylim=NULL,
     min_iter=NULL, max_iter=NULL,
     main_label="Boxplot cost evolution",
     iter_auto_ylim=3, steps=5, pos_cost_num=-3.1,
     pos_feat_num=-1.7, digits_plot=4, width_plot=12,
     height_plot=6, window=TRUE, ...)
```

### Arguments

<code>x</code>	An object of class "ga_parsimony".
<code>general_cex</code>	Main text scale.
<code>min_ylim</code>	Min limit on the y-axis.
<code>max_ylim</code>	Max limit on the y-axis.
<code>min_iter</code>	Min GA iteration to visualize.
<code>max_iter</code>	Max GA iteration to visualize.
<code>main_label</code>	Main plot title.
<code>iter_auto_ylim</code>	If it is not NULL, GA iteration to choose the min limit of y-axis.
<code>steps</code>	Number of divisions in y-axis.
<code>pos_cost_num</code>	Relative position of numbers in cost axis.
<code>pos_feat_num</code>	Relative position of numbers in feature axis.
<code>digits_plot</code>	Number of digits to visualize.
<code>width_plot</code>	Figure width in inches.
<code>height_plot</code>	Figure height in inches.
<code>window</code>	If TRUE shows a new window.
<code>...</code>	Further arguments, currently not used.

### Details

Plot method shows the evolution of validation and testing errors, and the number of model features selected of elitists. White and grey box-plots represent validation and testing errors of elitists evolution, respectively. Continuous and dashed-dotted lines show the validation and testing error of the best individual for each generation, respectively. Finally, the shaded area delimits the maximum and minimum number of features, and the dashed line, the number fo features of the best individual.

**Value**

The method invisibly return a list with the elistists validation error, testing error and model complexity in the whole GA process.

summary.ga\_parsimony-method

*Summary for GA-PARSIMONY*

---

**Description**

Summary method for class [ga\\_parsimony-class](#).

**Usage**

```
## S4 method for signature 'ga_parsimony'  
summary(object, ...)  
## S3 method for class 'summary.ga_parsimony'  
print(x, digits = getOption("digits"), ...)
```

**Arguments**

object	an object of class <a href="#">ga_parsimony-class</a> .
x	an object of class <code>summary.ga_parsimony</code> .
digits	number of significant digits.
...	further arguments passed to or from other methods.

**Value**

The summary function returns an object of class [ga\\_parsimony-class](#) which can be printed by the corresponding print method. The function also returns invisibly a list with the information from the genetic algorithm search.
