

Package ‘jtools’

May 8, 2018

Type Package

Title Analysis and Presentation of Social Scientific Data

Version 1.0.0

Description This is a collection of tools that the author (Jacob) has written for the purpose of more efficiently understanding and sharing the results of (primarily) regression analyses. There are a number of functions focused specifically on the interpretation and presentation of interactions. Just about everything supports models from the survey package.

add_gridlines	<i>Add and remove gridlines</i>
---------------	---------------------------------

Description

These are convenience wrappers for editing `ggplot2::theme()`'s `panel.grid.major` and `panel.grid.minor` parameters with sensible defaults.

Usage

```

add_gridlines(x = TRUE, y = TRUE, minor = TRUE)

add_x_gridlines(minor = TRUE)

add_y_gridlines(minor = TRUE)

drop_gridlines(x = TRUE, y = TRUE, minor.only = FALSE)

drop_x_gridlines(minor.only = FALSE)

drop_y_gridlines(minor.only = FALSE)

```

Arguments

x	Apply changes to the x axis?
y	Apply changes to the y axis?
minor	Add minor gridlines in addition to major?
minor.only	Remove only the minor gridlines?

cat_plot

Plot interaction effects between categorical predictors.

Description

cat_plot is a complementary function to [interact_plot\(\)](#) that is designed for plotting interactions when both predictor and moderator(s) are categorical (or, in R terms, factors).

Usage

```

cat_plot(model, pred, modx = NULL, mod2 = NULL, data = NULL,
  geom = c("point", "line", "bar", "boxplot"), predvals = NULL,
  modxvals = NULL, mod2vals = NULL, interval = TRUE,
  plot.points = FALSE, point.shape = FALSE, vary.lty = FALSE,
  centered = "all", int.type = c("confidence", "prediction"),
  int.width = 0.95, line.thickness = 1, point.size = 1,
  pred.point.size = 3.5, jitter = 0.1, geom.alpha = NULL,
  dodge.width = NULL, errorbar.width = NULL, interval.geom = c("errorbar",
  "linerange"), outcome.scale = "response", robust = FALSE,
  cluster = NULL, vcov = NULL, pred.labels = NULL, modx.labels = NULL,
  mod2.labels = NULL, set.offset = 1, x.label = NULL, y.label = NULL,
  main.title = NULL, legend.main = NULL, color.class = "CUD Bright", ...)

```

Arguments

model	A regression model. The function is tested with <code>lm</code> , <code>glm</code> , <code>svyglm</code> , <code>merMod</code> , <code>rq</code> , <code>brmsfit</code> , <code>stanreg</code> models. Models from other classes may work as well but are not officially supported. The model should include the interaction of interest.
pred	A categorical predictor variable that will appear on the x-axis.
modx	A categorical moderator variable.
mod2	For three-way interactions, the second categorical moderator.
data	Optional, default is <code>NULL</code> . You may provide the data used to fit the model. This can be a better way to get mean values for centering and can be crucial for models with variable transformations in the formula (e.g., <code>log(x)</code>) or polynomial terms (e.g., <code>poly(x, 2)</code>). You will see a warning if the function detects problems that would likely be solved by providing the data with this argument and the function will attempt to retrieve the original data from the global environment.
geom	<p>What type of plot should this be? There are several options here since the best way to visualize categorical interactions varies by context. Here are the options:</p> <ul style="list-style-type: none"> • "point": The default. Simply plot the point estimates. You may want to use <code>point.shape = TRUE</code> with this and you should also consider <code>interval = TRUE</code> to visualize uncertainty. • "line": This connects observations across levels of the <code>pred</code> variable with a line. This is a good option when the <code>pred</code> variable is ordinal (ordered). You may still consider <code>point.shape = TRUE</code> and <code>interval = TRUE</code> is still a good idea. • "bar": A bar chart. Some call this a "dynamite plot." Many applied researchers advise against this type of plot because it does not represent the distribution of the observed data or the uncertainty of the predictions very well. It is best to at least use the <code>interval = TRUE</code> argument with this <code>geom</code>. • "boxplot": This <code>geom</code> plots a dot and whisker plot. These can be useful for understanding the distribution of the observed data without having to plot all the observed points (especially helpful with larger data sets). However, it is important to note the boxplots are not based on the model whatsoever.
predvals	Which values of the predictor should be included in the plot? By default, all levels are included.
modxvals	<p>For which values of the moderator should lines be plotted? Default is <code>NULL</code>. If <code>NULL</code>, then the customary ± 1 standard deviation from the mean as well as the mean itself are used for continuous moderators. If "plus-minus", plots lines when the moderator is at ± 1 standard deviation without the mean. You may also choose "terciles" to split the data into equally-sized groups and choose the point at the mean of each of those groups.</p> <p>If the moderator is a factor variable and <code>modxvals</code> is <code>NULL</code>, each level of the factor is included. You may specify any subset of the factor levels (e.g., <code>c("Level 1", "Level 3")</code>) as long as there is more than 1. The levels will be plotted in the order you provide them, so this can be used to reorder levels as well.</p>

mod2vals	For which values of the second moderator should the plot be faceted by? That is, there will be a separate plot for each level of this moderator. Defaults are the same as modxvals.
interval	Logical. If TRUE, plots confidence/prediction intervals.
plot.points	Logical. If TRUE, plots the actual data points as a scatterplot on top of the interaction lines. Note that if geom = "bar", this will cause the bars to become transparent so you can see the points.
point.shape	For plotted points—either of observed data or predicted values with the "point" or "line" geoms—should the shape of the points vary by the values of the factor? This is especially useful if you aim to be black and white printing- or colorblind-friendly.
vary.lty	Should the resulting plot have different shapes for each line in addition to colors? Defaults to TRUE.
centered	A vector of quoted variable names that are to be mean-centered. If "all", all non-focal predictors are centered. You may instead pass a character vector of variables to center. User can also use "none" to base all predictions on variables set at 0. The response variable, pred, modx, and mod2 variables are never centered.
int.type	Type of interval to plot. Options are "confidence" or "prediction". Default is confidence interval.
int.width	How large should the interval be, relative to the standard error? The default, .95, corresponds to roughly 1.96 standard errors and a .05 alpha level for values outside the range. In other words, for a confidence interval, .95 is analogous to a 95% confidence interval.
line.thickness	How thick should the plotted lines be? Default is 1.1; ggplot's default is 1.
point.size	What size should be used for observed data when plot.points is TRUE? Default is 2.
pred.point.size	If TRUE and geom is "point" or "line", sets the size of the predicted points. Default is 3.5. Note the distinction from point.size, which refers to the observed data points.
jitter	How much should plot.points observed values be "jittered" via <code>ggplot2::position_jitter()</code> ? When there are many points near each other, jittering moves them a small amount to keep them from totally overlapping. In some cases, though, it can add confusion since it may make points appear to be outside the boundaries of observed values or cause other visual issues. Default is 0.1, but increase as needed if your points are overlapping too much or set to 0 for no jitter. If the argument is a vector with two values, then the first is assumed to be the jitter for width and the second for the height.
geom.alpha	What should the alpha aesthetic be for the plotted lines/bars? Default is NULL, which means it is set depending on the value of geom and plot.points.
dodge.width	What should the width argument to <code>ggplot2::position_dodge()</code> be? Default is NULL, which means it is set depending on the value of geom.
errorbar.width	How wide should the error bars be? Default is NULL, meaning it is set depending on the value geom. Ignored if interval is FALSE.

interval.geom	For categorical by categorical interactions. One of "errorbar" or "linrange". If the former, <code>ggplot2::geom_errorbar()</code> is used. If the latter, <code>ggplot2::geom_linrange()</code> is used.
outcome.scale	For nonlinear models (i.e., GLMs), should the outcome variable be plotted on the link scale (e.g., log odds for logit models) or the original scale (e.g., predicted probabilities for logit models)? The default is "response", which is the original scale. For the link scale, which will show straight lines rather than curves, use "link".
robust	Should robust standard errors be used to find confidence intervals for supported models? Default is FALSE, but you should specify the type of sandwich standard errors if you'd like to use them (i.e., "HC0", "HC1", and so on). If TRUE, defaults to "HC3" standard errors.
cluster	For clustered standard errors, provide the column name of the cluster variable in the input data frame (as a string). Alternately, provide a vector of clusters.
vcov	Optional. You may supply the variance-covariance matrix of the coefficients yourself. This is useful if you are using some method for robust standard error calculation not supported by the sandwich package.
pred.labels	A character vector of equal length to the number of factor levels of the predictor (or number specified in predvals). If NULL, the default, the factor labels are used.
modx.labels	A character vector of labels for each level of the moderator values, provided in the same order as the modxvals argument. If NULL, the values themselves are used as labels unless modxvals is also NULL. In that case, "+1 SD" and "-1 SD" are used.
mod2.labels	A character vector of labels for each level of the 2nd moderator values, provided in the same order as the mod2vals argument. If NULL, the values themselves are used as labels unless mod2vals is also NULL. In that case, "+1 SD" and "-1 SD" are used.
set.offset	For models with an offset (e.g., Poisson models), sets an offset for the predicted values. All predicted values will have the same offset. By default, this is set to 1, which makes the predicted values a proportion. See details for more about offset support.
x.label	A character object specifying the desired x-axis label. If NULL, the variable name is used.
y.label	A character object specifying the desired y-axis label. If NULL, the variable name is used.
main.title	A character object that will be used as an overall title for the plot. If NULL, no main title is used.
legend.main	A character object that will be used as the title that appears above the legend. If NULL, the name of the moderating variable is used.
color.class	Any palette argument accepted by <code>scale_colour_brewer</code> . Default is "Set2". You may also simply supply a vector of colors accepted by <code>ggplot2</code> and of equal length to the number of moderator levels.
...	extra arguments passed to <code>make_predictions</code>

Details

This function provides a means for plotting conditional effects for the purpose of exploring interactions in the context of regression. You must have the package `ggplot2` installed to benefit from these plotting functions.

The function is designed for two and three-way interactions. For additional terms, the `effects` package may be better suited to the task.

This function supports nonlinear and generalized linear models and by default will plot them on their original scale (`outcome.scale = "response"`).

While mixed effects models from `lme4` are supported, only the fixed effects are plotted. `lme4` does not provide confidence intervals, so they are not supported with this function either.

Note: to use transformed predictors, e.g., `log(variable)`, provide only the variable name to `pred`, `modx`, or `mod2` and supply the original data separately to the `data` argument.

Info about offsets:

Offsets are partially supported by this function with important limitations. First of all, only a single offset per model is supported. Second, it is best in general to specify offsets with the `offset` argument of the model fitting function rather than in the formula. You are much more likely to have success if you provide the data used to fit the model with the `data` argument.

Value

The functions returns a `ggplot` object, which can be treated like a user-created plot and expanded upon as such.

See Also

Other interaction tools: [interact_plot](#), [johnson_neyman](#), [probe_interaction](#), [sim_slopes](#)

Examples

```
library(ggplot2)
fit <- lm(price ~ cut * color, data = diamonds)
cat_plot(fit, pred = color, modx = cut, interval = TRUE)

# 3-way interaction

## Will first create a couple dichotomous factors to ensure full rank
mpg2 <- mpg
mpg2$auto <- "auto"
mpg2$auto[mpg2$trans %in% c("manual(m5)", "manual(m6)")] <- "manual"
mpg2$auto <- factor(mpg2$auto)
mpg2$fwd <- "2wd"
mpg2$fwd[mpg2$drv == "4"] <- "4wd"
mpg2$fwd <- factor(mpg2$fwd)
## Drop the two cars with 5 cylinders (rest are 4, 6, or 8)
mpg2 <- mpg2[mpg2$cyl != "5",]
mpg2$cyl <- factor(mpg2$cyl)
## Fit the model
```

```
fit3 <- lm(cty ~ cyl * fwd * auto, data = mpg2)

# The line geom looks good for an ordered factor predictor
cat_plot(fit3, pred = cyl, modx = fwd, mod2 = auto, geom = "line",
  interval = TRUE)
```

center

Mean-center vectors, data frames, and survey designs

Description

This function is a wrapper around [gscale\(\)](#) that is configured to mean-center variables without affecting the scaling of those variables.

Usage

```
center(data = NULL, vars = NULL, binary.inputs = "center",
  binary.factors = TRUE, weights = NULL)
```

Arguments

data	A data frame or survey design. Only needed if you would like to rescale multiple variables at once. If <code>x = NULL</code> , all columns will be rescaled. Otherwise, <code>x</code> should be a vector of variable names. If <code>x</code> is a numeric vector, this argument is ignored.
vars	If <code>data</code> is a <code>data.frame</code> or similar, you can scale only select columns by providing a vector column names to this argument.
binary.inputs	Options for binary variables. Default is <code>center</code> ; <code>0/1</code> keeps original scale; <code>-0.5/0.5</code> rescales 0 as -0.5 and 1 as 0.5; <code>center</code> subtracts the mean; and <code>full</code> subtracts the mean and divides by 2 sd.
binary.factors	Coerce two-level factors to numeric and apply scaling functions to them? Default is <code>TRUE</code> .
weights	A vector of weights equal in length to <code>x</code> . If iterating over a data frame, the weights will need to be equal in length to all the columns to avoid errors. You may need to remove missing values before using the weights.

Details

Some more information can be found in the documentation for [gscale\(\)](#)

Value

A transformed version of the data argument.

See Also

Other standardization, scaling, and centering tools: [center_mod](#), [gscale](#), [scale_mod](#), [standardize](#)

Examples

```
# Standardize just the "qsec" variable in mtcars
standardize(mtcars, vars = "qsec")
```

center_mod

*Center variables in fitted regression models***Description**

center_mod (previously known as center_lm) takes fitted regression models and mean-centers the continuous variables in the model to aid interpretation, especially in the case of models with interactions. It is a wrapper to [scale_mod](#).

Usage

```
center_mod(model, binary.inputs = "0/1", center.response = FALSE,
  data = NULL,
  apply.weighted.contrasts = getOption("jtools-weighted.contrasts", FALSE))
```

Arguments

- | | |
|--------------------------|---|
| model | A regression model of type <code>lm</code> , <code>glm</code> , or <code>svyglm</code> ; others may work as well but have not been tested. |
| binary.inputs | Options for binary variables. Default is <code>0/1</code> ; <code>0/1</code> keeps original scale; <code>-0.5, 0.5</code> rescales 0 as -0.5 and 1 as 0.5; <code>center</code> subtracts the mean; and <code>full</code> treats them like other continuous variables. |
| center.response | Should the response variable also be centered? Default is <code>FALSE</code> . |
| data | If you provide the data used to fit the model here, that data frame is used to re-fit the model instead of the <code>stats::model.frame()</code> of the model. This is particularly useful if you have variable transformations or polynomial terms specified in the formula. |
| apply.weighted.contrasts | Factor variables cannot be scaled, but you can set the contrasts such that the intercept in a regression model will reflect the true mean (assuming all other variables are centered). If set to <code>TRUE</code> , the argument will apply weighted effects coding to all factors. This is similar to the R default effects coding, but weights according to how many observations are at each level. An adapted version of <code>wec::contr.wec()</code> from the <code>wec</code> package is used to do this. See that package's documentation and/or Grotenhuis et al. (2016) for more info. |

Details

This function will mean-center all continuous variables in a regression model for ease of interpretation, especially for those models that have interaction terms. The mean for `svyglm` objects is calculated using `svymean`, so reflects the survey-weighted mean. The weight variables in `svyglm` are not centered, nor are they in other `lm` family models.

This function re-estimates the model, so for large models one should expect a runtime equal to the first run.

Value

The functions returns a `lm` or `glm` object, inheriting from whichever class was supplied.

effect_plot

Plot simple effects in regression models

Description

`effect_plot()` plots regression paths. The plotting is done with `ggplot2` rather than base graphics, which some similar functions use.

Usage

```
effect_plot(model, pred, centered = "all", plot.points = FALSE,
  interval = FALSE, data = NULL, int.type = c("confidence", "prediction"),
  int.width = 0.95, outcome.scale = "response", robust = FALSE,
  cluster = NULL, vcov = NULL, set.offset = 1, x.label = NULL,
  y.label = NULL, pred.labels = NULL, main.title = NULL,
  color.class = NULL, line.thickness = 1.1, point.size = 2, jitter = 0,
  rug = FALSE, rug.sides = "b", ...)
```

Arguments

<code>model</code>	A regression model. The function is tested with <code>lm</code> , <code>glm</code> , <code>svyglm</code> , <code>merMod</code> , <code>rq</code> , <code>brmsfit</code> , <code>stanreg</code> models. Models from other classes may work as well but are not officially supported. The model should include the interaction of interest.
<code>pred</code>	The name of the predictor variable involved in the interaction. This can be a bare name or string.
<code>centered</code>	A vector of quoted variable names that are to be mean-centered. If "all", all non-focal predictors are centered. You may instead pass a character vector of variables to center. User can also use "none" to base all predictions on variables set at 0. The response variable, <code>pred</code> , <code>modx</code> , and <code>mod2</code> variables are never centered.
<code>plot.points</code>	Logical. If TRUE, plots the actual data points as a scatterplot on top of the interaction lines. The color of the dots will be based on their moderator value.
<code>interval</code>	Logical. If TRUE, plots confidence/prediction intervals around the line using <code>geom_ribbon</code> .
<code>data</code>	Optional, default is NULL. You may provide the data used to fit the model. This can be a better way to get mean values for centering and can be crucial for models with variable transformations in the formula (e.g., <code>log(x)</code>) or polynomial terms (e.g., <code>poly(x, 2)</code>). You will see a warning if the function detects problems that would likely be solved by providing the data with this argument and the function will attempt to retrieve the original data from the global environment.

<code>int.type</code>	Type of interval to plot. Options are "confidence" or "prediction". Default is confidence interval.
<code>int.width</code>	How large should the interval be, relative to the standard error? The default, .95, corresponds to roughly 1.96 standard errors and a .05 alpha level for values outside the range. In other words, for a confidence interval, .95 is analogous to a 95% confidence interval.
<code>outcome.scale</code>	For nonlinear models (i.e., GLMs), should the outcome variable be plotted on the link scale (e.g., log odds for logit models) or the original scale (e.g., predicted probabilities for logit models)? The default is "response", which is the original scale. For the link scale, which will show straight lines rather than curves, use "link".
<code>robust</code>	Should robust standard errors be used to find confidence intervals for supported models? Default is FALSE, but you should specify the type of sandwich standard errors if you'd like to use them (i.e., "HC0", "HC1", and so on). If TRUE, defaults to "HC3" standard errors.
<code>cluster</code>	For clustered standard errors, provide the column name of the cluster variable in the input data frame (as a string). Alternately, provide a vector of clusters.
<code>vcov</code>	Optional. You may supply the variance-covariance matrix of the coefficients yourself. This is useful if you are using some method for robust standard error calculation not supported by the sandwich package.
<code>set.offset</code>	For models with an offset (e.g., Poisson models), sets an offset for the predicted values. All predicted values will have the same offset. By default, this is set to 1, which makes the predicted values a proportion. See details for more about offset support.
<code>x.label</code>	A character object specifying the desired x-axis label. If NULL, the variable name is used.
<code>y.label</code>	A character object specifying the desired y-axis label. If NULL, the variable name is used.
<code>pred.labels</code>	A character vector of 2 labels for the predictor if it is a 2-level factor or a continuous variable with only 2 values. If NULL, the default, the factor labels are used.
<code>main.title</code>	A character object that will be used as an overall title for the plot. If NULL, no main title is used.
<code>color.class</code>	See jtools_colors for details on the types of arguments accepted. Default is "CUD Bright" for factor moderators, "Blues" for +/- SD and user-specified modxvals values.
<code>line.thickness</code>	How thick should the plotted lines be? Default is 1.1; ggplot's default is 1.
<code>point.size</code>	What size should be used for observed data when <code>plot.points</code> is TRUE? Default is 2.
<code>jitter</code>	How much should <code>plot.points</code> observed values be "jittered" via <code>ggplot2::position_jitter()</code> ? When there are many points near each other, jittering moves them a small amount to keep them from totally overlapping. In some cases, though, it can add confusion since it may make points appear to be outside the boundaries of observed values or cause other visual issues. Default is 0, but try various small values

	(e.g., 0.1) and increase as needed if your points are overlapping too much. If the argument is a vector with two values, then the first is assumed to be the jitter for width and the second for the height.
rug	Show a rug plot in the margins? This uses <code>ggplot2::geom_rug()</code> to show the distribution of the predictor (top/bottom) and/or response variable (left/right) in the original data. Default is FALSE.
rug.sides	On which sides should rug plots appear? Default is "b", meaning bottom. "t" and/or "b" show the distribution of the predictor while "l" and/or "r" show the distribution of the response. "bl" is a good option to show both the predictor and response.
...	extra arguments passed to <code>make_predictions</code>

Details

This function provides a means for plotting effects for the purpose of exploring regression estimates. You must have the package `ggplot2` installed to benefit from these plotting functions.

By default, all numeric predictors other than the one specified in the `pred` argument are mean-centered, which usually produces more intuitive plots. This only affects the y-axis in linear models, but may be especially important/influential in non-linear/generalized linear models.

This function supports nonlinear and generalized linear models and by default will plot them on their original scale (`outcome.scale = "response"`).

While mixed effects models from `lme4` are supported, only the fixed effects are plotted. `lme4` does not provide confidence intervals, so they are not supported with this function either.

Note: to use transformed predictors, e.g., $\log(x)$, or polynomials, e.g., $\text{poly}(x, 2)$, provide the raw variable name (`x`) to the `pred =` argument. You will need to input the data frame used to fit the model with the `data =` argument.

Value

The functions returns a `ggplot` object, which can be treated like a user-created plot and expanded upon as such.

  family = binomial,
  control = glmerControl("bobyqa"))
effect_plot(mv, pred = Anger)

## End(Not run)

```

 export_summs

Export regression summaries to tables

Description

This function allows users to use the features of `summ()` (e.g., standardization, robust standard errors) in the context of shareable HTML, LaTeX, and Microsoft Word tables. It relies heavily on `huxtable::huxreg()` to do the table formatting. This is particularly useful for putting the results of multiple models into a single table.

Usage

```

export_summs(..., error_format = "{std.error}", error_pos = c("below",
  "right", "same"), ci_level = 0.95, statistics = NULL,
  model.names = NULL, coefs = NULL, to.file = NULL, file.name = NULL)

```

Arguments

... At minimum, a regression object(s). See details for more arguments.

error_format	Which of standard error, confidence intervals, test statistics, or p values should be used to express uncertainty of estimates for regression coefficients? See details for more info. Default: "(std.error)"
error_pos	Where should the error statistic defined in error_style be placed relative to the coefficient estimate? Default: "below"
ci_level	If reporting confidence intervals, what should the confidence level be? By default, it is .95 if confidence intervals are requested in error_format.
statistics	Which model summary statistics should be included? See huxreg for more on usage. The default for this function depends on the model type. See details for more on the defaults by model type.
model.names	If you want to give your model(s) names at the top of each column, provide them here as a character vector. Otherwise, they will just be labeled by number. Default: NULL
coefs	If you want to include only a subset of the coefficients in the table, specify them here in a character vector. If you want the table to show different names for the coefficients, give a named vector where the names are the preferred coefficient names. See details for more.
to.file	Export the table to a Microsoft Word, PDF, or HTML document? This functionality relies on <code>huxtable</code> 's quick_ functions (<code>huxtable::quick_docx()</code> , <code>huxtable::quick_pdf()</code> , <code>huxtable::quick_html()</code> , <code>huxtable::quick_xlsx()</code>). Acceptable arguments are "Word" or "docx" (equivalent), "pdf", "html", or "xlsx". All are case insensitive. Default is NULL, meaning the table is not saved.
file.name	File name with (optionally) file path to save the file. Ignored if to.file is FALSE. Default: NULL

Details

There are many optional parameters not documented above. Any argument that you would want to pass to `summ()`, for instance, will be used. Of particular interest may be the robust and scale arguments. Note that some `summ` arguments may not have any bearing on the table output.

The default model summary statistics reporting follows this logic:

- `summ.lm = c(N = "nobs", R2 = "r.squared")`,
- `summ.glm = c(N = "nobs", AIC = "AIC", BIC = "BIC")`,
- `summ.svyglm = c(N = "nobs", R2 = "r.squared")`,
- `summ.merMod = c(N = "nobs", AIC = "AIC", BIC = "BIC", `R2 (fixed)` = "r.squared")`,
- `summ.rq = c(N = "nobs", tau = "tau", R1 = "r.1", AIC = "AIC", BIC = "BIC")`

Be sure to look at the `summ()` documentation for more on the calculation of these and other statistics, especially for mixed models.

If you set `statistics = "all"`, then the `statistics` argument passed to `huxreg` will be NULL, which reports whichever model statistics are available via `glance`. If you want no model summary statistics, set the argument to `character(0)`.

You have a few options for the `error_format` argument. You can include anything returned by `broom::tidy()` (see also `tidy.summ()`). For the most part, you will be interested in `std.error`

(standard error), statistic (test statistic, e.g. t-value or z-value), p.value, or conf.high and conf.low, which correspond to the upper and lower bounds of the confidence interval for the estimate. Note that the default ci_level argument is .95, but you can alter that as desired.

To format the error statistics, simply put the statistics desired in curly braces wherever you want them in a character string. For example, if you want the standard error in parentheses, the argument would be "{std.error}", which is the default. Some other ideas:

- "{statistic}", which gives you the test statistic in parentheses.
- "{statistic}, p = {p.value}", which gives the test statistic followed by a "p=" p value all in parentheses. Note that you'll have to pay special attention to rounding if you do this to keep cells sufficiently narrow.
- "[{conf.low}, {conf.high}]", which gives the confidence interval in the standard bracket notation. You could also explicitly write the confidence level, e.g., "CI [{conf.low}, {conf.high}]".

For coefs, the argument is slightly different than what is default in huxreg. If you provide a named vector of coefficients, then the table will refer to the selected coefficients by the names of the vector rather than the coefficient names. For instance, if I want to include only the coefficients for the hp and mpg but have the table refer to them as "Horsepower" and "Miles/gallon", I'd provide the argument like this: c("Horsepower" = "hp", "Miles/gallon" = "mpg")

You can also pass any argument accepted by the `huxtable::huxreg()` function. A few that are likely to be oft-used are documented above, but visit huxreg's documentation for more info.

For info on converting the `huxtable::huxtable()` object to HTML or LaTeX, see huxtable's documentation.

Value

A huxtable.

Examples

```
states <- as.data.frame(state.x77)
fit1 <- lm(Income ~ Frost, data = states)
fit2 <- lm(Income ~ Frost + Illiteracy, data = states)
fit3 <- lm(Income ~ Frost + Illiteracy + Murder, data = states)

if (requireNamespace("huxtable")) {
  # Export all 3 regressions with "Model #" labels,
  # standardized coefficients, and robust standard errors
  export_summs(fit1, fit2, fit3,
               model.names = c("Model 1", "Model 2", "Model 3"),
               coefs = c("Frost Days" = "Frost",
                          "% Illiterate" = "Illiteracy",
                          "Murder Rate" = "Murder"),
               scale = TRUE, robust = TRUE)
```

```
}

```

gscale

Scale and/or center data, including survey designs

Description

gscale standardizes variables by dividing them by 2 standard deviations and mean-centering them by default. It contains options for handling binary variables separately. gscale() is a fork of [rescale](#) from the **arm** package—the key feature difference is that gscale() will perform the same functions for variables in [svydesign](#) objects. gscale() is also more user-friendly in that it is more flexible in how it accepts input.

Usage

```
gscale(data = NULL, vars = NULL, binary.inputs = "center",
       binary.factors = TRUE, n.sd = 2, center.only = FALSE,
       scale.only = FALSE, weights = NULL,
       apply.weighted.contrasts = getOption("jtools-weighted.contrasts", FALSE),
       x = NULL, messages = FALSE)
```

Arguments

data	A data frame or survey design. Only needed if you would like to rescale multiple variables at once. If <code>x = NULL</code> , all columns will be rescaled. Otherwise, <code>x</code> should be a vector of variable names. If <code>x</code> is a numeric vector, this argument is ignored.
vars	If <code>data</code> is a <code>data.frame</code> or similar, you can scale only select columns by providing a vector column names to this argument.
binary.inputs	Options for binary variables. Default is <code>center</code> ; <code>0/1</code> keeps original scale; <code>-0.5/0.5</code> rescales 0 as -0.5 and 1 as 0.5; <code>center</code> subtracts the mean; and <code>full</code> subtracts the mean and divides by 2 sd.
binary.factors	Coerce two-level factors to numeric and apply scaling functions to them? Default is <code>TRUE</code> .
n.sd	By how many standard deviations should the variables be divided by? Default for <code>gscale</code> is 2, like arm 's rescale . 1 is the more typical standardization scheme.
center.only	A logical value indicating whether you would like to mean -center the values, but not scale them.
scale.only	A logical value indicating whether you would like to scale the values, but not mean-center them.
weights	A vector of weights equal in length to <code>x</code> . If iterating over a data frame, the weights will need to be equal in length to all the columns to avoid errors. You may need to remove missing values before using the weights.

<code>apply.weighted.contrasts</code>	Factor variables cannot be scaled, but you can set the contrasts such that the intercept in a regression model will reflect the true mean (assuming all other variables are centered). If set to TRUE, the argument will apply weighted effects coding to all factors. This is similar to the R default effects coding, but weights according to how many observations are at each level. An adapted version of <code>wec::contr.wec()</code> from the <code>wec</code> package is used to do this. See that package's documentation and/or Grotenhuis et al. (2016) for more info.
<code>x</code>	Deprecated. Pass numeric vectors to data. Pass vectors of column names to vars.
<code>messages</code>	Print messages when variables are not processed due to being non-numeric or all missing? Default is FALSE.

Details

This function is adapted from the `rescale` function of the `arm` package. It is named `gscale()` after the popularizer of this scaling method, Andrew Gelman. By default, it works just like `rescale`. But it contains many additional options and can also accept multiple types of input without breaking a sweat.

Only numeric variables are altered when in a `data.frame` or survey design. Character variables, factors, etc. are skipped.

For those dealing with survey data, if you provide a `survey.design` object you can rest assured that the mean-centering and scaling is performed with help from the `svymean` and `svyvar` functions, respectively. It was among the primary motivations for creating this function. `gscale()` will not center or scale the weights variables defined in the survey design unless the user specifically requests them in the `x =` argument.

`j_summ` is a replacement for the `summary` function for regression models. On request, it will center and/or standardize variables before printing its output.

Other standardization, scaling, and centering tools: `center_mod`, `center`, `scale_mod`, `standardize`

Examples

```

x <- rnorm(10, 2, 1)
x2 <- rbinom(10, 1, .5)

# Basic use
gscale(x)
# Normal standardization
gscale(x, n.sd = 1)
# Scale only
gscale(x, scale.only = TRUE)
# Center only
gscale(x, center.only = TRUE)
# Binary inputs
gscale(x2, binary.inputs = "0/1")
gscale(x2, binary.inputs = "full") # treats it like a continous var
gscale(x2, binary.inputs = "-0.5/0.5") # keep scale, center at zero
gscale(x2, binary.inputs = "center") # mean center it

# Data frame as input
# loops through each numeric column
gscale(data = mtcars, binary.inputs = "-0.5/0.5")

# Specified vars in data frame
gscale(mtcars, vars = c("hp", "wt", "vs"), binary.inputs = "center")

# Weighted inputs

wts <- runif(10, 0, 1)
gscale(x, weights = wts)
# If using a weights column of data frame, give its name
mtcars$weights <- runif(32, 0, 1)
gscale(mtcars, weights = weights) # will skip over mtcars$weights
# If using a weights column of data frame, can still select variables
gscale(mtcars, vars = c("hp", "wt", "vs"), weights = weights)

# Survey designs
if (requireNamespace("survey")) {
  library(survey)
  data(api)
  ## Create survey design object
  dstrat <- svydesign(id = ~1, strata = ~stype, weights = ~pw,
                    data = apistrat, fpc=~fpc)
  # Creating test binary variable
  dstrat$variables$binary <- rbinom(200, 1, 0.5)

  gscale(data = dstrat, binary.inputs = "-0.5/0.5")
  gscale(data = dstrat, vars = c("api00", "meals", "binary"),
        binary.inputs = "-0.5/0.5")
}

```

interact_plot

Plot interaction effects in regression models

Description

`interact_plot` plots regression lines at user-specified levels of a moderator variable to explore interactions. The plotting is done with `ggplot2` rather than base graphics, which some similar functions use.

Usage

```
interact_plot(model, pred, modx, modxvals = NULL, mod2 = NULL,
  mod2vals = NULL, centered = "all", data = NULL, plot.points = FALSE,
  interval = FALSE, int.type = c("confidence", "prediction"),
  int.width = 0.95, outcome.scale = "response", linearity.check = FALSE,
  facet.modx = FALSE, robust = FALSE, cluster = NULL, vcov = NULL,
  set.offset = 1, x.label = NULL, y.label = NULL, pred.labels = NULL,
  modx.labels = NULL, mod2.labels = NULL, main.title = NULL,
  legend.main = NULL, color.class = NULL, line.thickness = 1.1,
  vary.lty = TRUE, point.size = 2, point.shape = FALSE, jitter = 0,
  rug = FALSE, rug.sides = "b", ...)
```

Arguments

- | | |
|-----------------------|--|
| <code>model</code> | A regression model. The function is tested with <code>lm</code> , <code>glm</code> , <code>svyglm</code> , <code>merMod</code> , <code>rq</code> , <code>brmsfit</code> , <code>stanreg</code> models. Models from other classes may work as well but are not officially supported. The model should include the interaction of interest. |
| <code>pred</code> | The name of the predictor variable involved in the interaction. This can be a bare name or string. |
| <code>modx</code> | The name of the moderator variable involved in the interaction. This can be a bare name or string. |
| <code>modxvals</code> | For which values of the moderator should lines be plotted? Default is <code>NULL</code> . If <code>NULL</code> , then the customary ± 1 standard deviation from the mean as well as the mean itself are used for continuous moderators. If <code>"plus-minus"</code> , plots lines when the moderator is at ± 1 standard deviation without the mean. You may also choose <code>"terciles"</code> to split the data into equally-sized groups and choose the point at the mean of each of those groups.

If the moderator is a factor variable and <code>modxvals</code> is <code>NULL</code> , each level of the factor is included. You may specify any subset of the factor levels (e.g., <code>c("Level 1", "Level 3")</code>) as long as there is more than 1. The levels will be plotted in the order you provide them, so this can be used to reorder levels as well. |
| <code>mod2</code> | Optional. The name of the second moderator variable involved in the interaction. This can be a bare name or string. |

mod2vals	For which values of the second moderator should the plot be faceted by? That is, there will be a separate plot for each level of this moderator. Defaults are the same as modxvals.
centered	A vector of quoted variable names that are to be mean-centered. If "all", all non-focal predictors are centered. You may instead pass a character vector of variables to center. User can also use "none" to base all predictions on variables set at 0. The response variable, pred, modx, and mod2 variables are never centered.
data	Optional, default is NULL. You may provide the data used to fit the model. This can be a better way to get mean values for centering and can be crucial for models with variable transformations in the formula (e.g., $\log(x)$) or polynomial terms (e.g., $\text{poly}(x, 2)$). You will see a warning if the function detects problems that would likely be solved by providing the data with this argument and the function will attempt to retrieve the original data from the global environment.
plot.points	Logical. If TRUE, plots the actual data points as a scatterplot on top of the interaction lines. The color of the dots will be based on their moderator value.
interval	Logical. If TRUE, plots confidence/prediction intervals around the line using geom_ribbon .
int.type	Type of interval to plot. Options are "confidence" or "prediction". Default is confidence interval.
int.width	How large should the interval be, relative to the standard error? The default, .95, corresponds to roughly 1.96 standard errors and a .05 alpha level for values outside the range. In other words, for a confidence interval, .95 is analogous to a 95% confidence interval.
outcome.scale	For nonlinear models (i.e., GLMs), should the outcome variable be plotted on the link scale (e.g., log odds for logit models) or the original scale (e.g., predicted probabilities for logit models)? The default is "response", which is the original scale. For the link scale, which will show straight lines rather than curves, use "link".
linearity.check	For two-way interactions only. If TRUE, plots a pane for each level of the moderator and superimposes a loess smoothed line (in gray) over the plot. This enables you to see if the effect is linear through the span of the moderator. See Hainmueller et al. (2016) in the references for more details on the intuition behind this. It is recommended that you also set plot.points = TRUE and use modxvals = "terciles" with this option.
facet.modx	Create separate panels for each level of the moderator? Default is FALSE, except when linearity.check is TRUE.
robust	Should robust standard errors be used to find confidence intervals for supported models? Default is FALSE, but you should specify the type of sandwich standard errors if you'd like to use them (i.e., "HC0", "HC1", and so on). If TRUE, defaults to "HC3" standard errors.
cluster	For clustered standard errors, provide the column name of the cluster variable in the input data frame (as a string). Alternately, provide a vector of clusters.

<code>vcov</code>	Optional. You may supply the variance-covariance matrix of the coefficients yourself. This is useful if you are using some method for robust standard error calculation not supported by the sandwich package.
<code>set.offset</code>	For models with an offset (e.g., Poisson models), sets an offset for the predicted values. All predicted values will have the same offset. By default, this is set to 1, which makes the predicted values a proportion. See details for more about offset support.
<code>x.label</code>	A character object specifying the desired x-axis label. If NULL, the variable name is used.
<code>y.label</code>	A character object specifying the desired x-axis label. If NULL, the variable name is used.
<code>pred.labels</code>	A character vector of 2 labels for the predictor if it is a 2-level factor or a continuous variable with only 2 values. If NULL, the default, the factor labels are used.
<code>modx.labels</code>	A character vector of labels for each level of the moderator values, provided in the same order as the <code>modxvals</code> argument. If NULL, the values themselves are used as labels unless <code>modxvals</code> is also NULL. In that case, "+1 SD" and "-1 SD" are used.
<code>mod2.labels</code>	A character vector of labels for each level of the 2nd moderator values, provided in the same order as the <code>mod2vals</code> argument. If NULL, the values themselves are used as labels unless <code>mod2vals</code> is also NULL. In that case, "+1 SD" and "-1 SD" are used.
<code>main.title</code>	A character object that will be used as an overall title for the plot. If NULL, no main title is used.
<code>legend.main</code>	A character object that will be used as the title that appears above the legend. If NULL, the name of the moderating variable is used.
<code>color.class</code>	See jtools_colors for details on the types of arguments accepted. Default is "CUD Bright" for factor moderators, "Blues" for +/- SD and user-specified <code>modxvals</code> values.
<code>line.thickness</code>	How thick should the plotted lines be? Default is 1.1; ggplot's default is 1.
<code>vary.lty</code>	Should the resulting plot have different shapes for each line in addition to colors? Defaults to TRUE.
<code>point.size</code>	What size should be used for observed data when <code>plot.points</code> is TRUE? Default is 2.
<code>point.shape</code>	For plotted points—either of observed data or predicted values with the "point" or "line" geoms—should the shape of the points vary by the values of the factor? This is especially useful if you aim to be black and white printing- or colorblind-friendly.
<code>jitter</code>	How much should <code>plot.points</code> observed values be "jittered" via <code>ggplot2::position_jitter()</code> ? When there are many points near each other, jittering moves them a small amount to keep them from totally overlapping. In some cases, though, it can add confusion since it may make points appear to be outside the boundaries of observed values or cause other visual issues. Default is 0, but try various small values (e.g., 0.1) and increase as needed if your points are overlapping too much. If the argument is a vector with two values, then the first is assumed to be the jitter for width and the second for the height.

<code>rug</code>	Show a rug plot in the margins? This uses <code>ggplot2::geom_rug()</code> to show the distribution of the predictor (top/bottom) and/or response variable (left/right) in the original data. Default is FALSE.
<code>rug.sides</code>	On which sides should rug plots appear? Default is "b", meaning bottom. "t" and/or "b" show the distribution of the predictor while "l" and/or "r" show the distribution of the response. "bl" is a good option to show both the predictor and response.
<code>...</code>	extra arguments passed to <code>make_predictions</code>

Details

This function provides a means for plotting conditional effects for the purpose of exploring interactions in regression models.

The function is designed for two and three-way interactions. For additional terms, the **effects** package may be better suited to the task.

This function supports nonlinear and generalized linear models and by default will plot them on their original scale (`outcome.scale = "response"`). To plot them on the linear scale, use `"link"` for `outcome.scale`.

While mixed effects models from `lme4` are supported, only the fixed effects are plotted. `lme4` does not provide confidence intervals, so they are not supported with this function either.

Note: to use transformed predictors, e.g., `log(variable)`, put its name in quotes or backticks in the argument.

Details on how observed data are split in multi-pane plots:

If you set `plot.points = TRUE` and request a multi-pane (facetted) plot either with a second moderator, `linearity.check = TRUE`, or `facet.modx = TRUE`, the observed data are split into as many groups as there are panes and plotted separately. If the moderator is a factor, then the way this happens will be very intuitive since it's obvious which values go in which pane. The rest of this section will address the case of continuous moderators.

My recommendation is that you use `modxvals = "terciles"` or `mod2vals = "terciles"` when you want to plot observed data on multi-pane plots. When you do, the data are split into three approximately equal-sized groups with the lowest third, middle third, and highest third of the data split accordingly. You can replicate this procedure using `Hmisc::cut2()` with `g = 3` from the `Hmisc` package. Sometimes, the groups will not be equal in size because the number of observations is not divisible by 3 and/or there are multiple observations with the same value at one of the cut points.

Otherwise, a more ad hoc procedure is used to split the data. Quantiles are found for each `mod2vals` or `modxvals` value. These are not the quantiles used to split the data, however, since we want the plotted lines to represent the slope at a typical value in the group. The next step, then, is to take the mean of each pair of neighboring quantiles and use these as the cut points.

For example, if the `mod2vals` are at the 25th, 50th, and 75th percentiles of the distribution of the moderator, the data will be split at the 37.5th and 62.5th percentiles. When the variable is normally distributed, this will correspond fairly closely to using terciles.

Info about offsets:

Offsets are partially supported by this function with important limitations. First of all, only a single offset per model is supported. Second, it is best in general to specify offsets with the `offset` argument

of the model fitting function rather than in the formula. You are much more likely to have success if you provide the data used to fit the model with the `data` argument.

Value

The function returns a `ggplot` object, which can be treated like a user-created plot and expanded upon as such.

interact_plot(regmodel, pred = ell, modx = meals)
}

# With lme4
## Not run:
library(lme4)
data(VerbAgg)
mv <- glmer(r2 ~ Anger * mode + (1 | item), data = VerbAgg,
  family = binomial,
  control = glmerControl("bobyqa"))
interact_plot(mv, pred = Anger, modx = mode)

## End(Not run)

```

johnson_neyman

Calculate Johnson-Neyman intervals for 2-way interactions

Description

johnson_neyman finds so-called "Johnson-Neyman" intervals for understanding where simple slopes are significant in the context of interactions in multiple linear regression.

Usage

```

johnson_neyman(model, pred, modx, vmat = NULL, alpha = 0.05, plot = TRUE,
  control.fdr = FALSE, line.thickness = 0.5, df = "residual",
  digits = getOption("jtools-digits", 2))

```

Arguments

model	A regression model. It is tested with <code>lm</code> , <code>glm</code> , and <code>svyglm</code> objects, but others may work as well. It should contain the interaction of interest. Be aware that just because the computations work, this does not necessarily mean the procedure is appropriate for the type of model you have.
pred	The predictor variable involved in the interaction.
modx	The moderator variable involved in the interaction.
vmat	Optional. You may supply the variance-covariance matrix of the coefficients yourself. This is useful if you are using robust standard errors, as you could if using the sandwich package.
alpha	The alpha level. By default, the standard 0.05.
plot	Should a plot of the results be printed? Default is TRUE. The <code>ggplot2</code> object is returned either way.

<code>control.fdr</code>	Logical. Use the procedure described in Esarey & Sumner (2017) to limit the false discovery rate? Default is FALSE. See details for more on this method.
<code>line.thickness</code>	How thick should the predicted line be? This is passed to <code>geom_path</code> as the <code>size</code> argument, but because of the way the line is created, you cannot use <code>geom_path</code> to modify the output plot yourself.
<code>df</code>	How should the degrees of freedom be calculated for the critical test statistic? Previous versions used the large sample approximation; if <code>alpha</code> was .05, the critical test statistic was 1.96 regardless of sample size and model complexity. The default is now "residual", meaning the same degrees of freedom used to calculate <code>p</code> values for regression coefficients. You may instead choose any number or "normal", which reverts to the previous behavior. The argument is not used if <code>control.fdr = TRUE</code> .
<code>digits</code>	An integer specifying the number of digits past the decimal to report in the output. Default is 2. You can change the default number of digits for all <code>jtools</code> functions with <code>options("jtools-digits" = digits)</code> where <code>digits</code> is the desired number.

Details

The interpretation of the values given by this function is important and not always immediately intuitive. For an interaction between a predictor variable and moderator variable, it is often the case that the slope of the predictor is statistically significant at only some values of the moderator. For example, perhaps the effect of your predictor is only significant when the moderator is set at some high value.

The Johnson-Neyman interval provides the two values of the moderator at which the slope of the predictor goes from non-significant to significant. Usually, the predictor's slope is only significant *outside* of the range given by the function. The output of this function will make it clear either way.

One weakness of this method of probing interactions is that it is analagous to making multiple comparisons without any adjustment to the alpha level. Esarey & Sumner (2017) proposed a method for addressing this, which is implemented in the `interactionTest` package. This function implements that procedure with modifications to the `interactionTest` code (that package is not required to use this function). If you set `control.fdr = TRUE`, an alternative *t* statistic will be calculated based on your specified alpha level and the data. This will always be a more conservative test than when `control.fdr = FALSE`. The printed output will report the calculated critical *t* statistic.

This technique is not easily ported to 3-way interaction contexts. You could, however, look at the J-N interval at two different levels of a second moderator. This does forgo a benefit of the J-N technique, which is not having to pick arbitrary points. If you want to do this, just use the `sim_slopes` function's ability to handle 3-way interactions and request Johnson-Neyman intervals for each.

Value

<code>bounds</code>	The two numbers that make up the interval.
<code>cbands</code>	A dataframe with predicted values of the predictor's slope and lower/upper bounds of confidence bands if you would like to make your own plots
<code>plot</code>	The <code>ggplot</code> object used for plotting. You can tweak the plot like you could any other from <code>ggplot</code> .

jtools_colors

Color palettes in jtools functions

Description

jtools combines several options into the `color.class` argument in plotting functions.

Details

The argument to `color.class` in functions like `interact_plot`, `cat_plot`, `plot_coefs`, and others is very flexible but may also cause confusion.

If you provide an argument of length 1, it is assumed that you are naming a palette. jtools provides 6 color palettes design for qualitative data. 4 of the 6 are based on Paul Tol's suggestions (see references) and are meant to both optimize your ability to quickly differentiate the colors and to be distinguishable to colorblind people. These are called "Qual1", "Qual2", "Qual3", "CUD", "CUD Bright", and "Rainbow". Each of the "Qual" schemes comes from Paul Tol. "Rainbow" is Paul Tol's compromise rainbow color scheme that is fairly differentiable for colorblind people and when rendered in grayscale. "CUD Bright" is a brightened and reordered version of Okabe and

Ito's suggestions for 'Color Universal Design' while "CUD" is their exact scheme (see references). "CUD Bright" is the default for qualitative scales in `jtools` functions.

You may also provide any color palette supported by `RColorBrewer`. See all of those options at `RColorBrewer::brewer.pal()`'s documentation. If you provide one of `RColorBrewer`'s sequential palettes, like "Blues", `jtools` automatically requests one more color than needed from `brewer.pal` and then drops the lightest color. My experience is that those scales tend to give one color that is too light to easily differentiate against a white background.

Lastly, you may provide colors by name. This must be a vector of the same length as whatever it is the colors will correspond to (e.g., 3 colors for 3 values of the moderator in `interact_plot`). The format must be one understood by `ggplot2`'s manual scale functions. This basically means it needs to be in hex format (e.g., "#000000") or one of the many names R understands (e.g., "red"; use `colors()` to see all of those options).

References

Paul Tol's site is what is used to derive 4 of the 6 `jtools`-specific palettes: <https://personal.sron.nl/~pault/>

Okabe and Ito's palette inspired "CUD Bright", though "CUD Bright" is not exactly the same. "CUD" is the same. See <http://jfly.iam.u-tokyo.ac.jp/color/> for more.

j_summ

Regression summaries with options

Description

`j_summ` is an alias for `summ`. To get specific documentation, choose the appropriate link to the type of model that you want to summarize from the details section.

Usage

```
j_summ(model, ...)
```

Arguments

<code>model</code>	A <code>lm</code> , <code>glm</code> , <code>svyglm</code> , or <code>merMod</code> object.
<code>...</code>	Other arguments to be passed to the model-specific function.

Details

- [summ.lm](#)
- [summ.glm](#)
- [summ.svyglm](#)
- [summ.merMod](#)

make_predictions	<i>Generate predicted data for plotting results of regression models</i>
------------------	--

Description

This is an alternate interface to the underlying tools that make up `interact_plot()`, `effect_plot()`, and `cat_plot()`. `make_predictions` creates the data to be plotted and adds information to the original data to make it more amenable for plotting with the predicted data.

Usage

```
make_predictions(model, ...)
```

```
## Default S3 method:
```

```
make_predictions(model, pred, predvals = NULL,
  modx = NULL, modxvals = NULL, mod2 = NULL, mod2vals = NULL,
  centered = "all", data = NULL, plot.points = FALSE, interval = FALSE,
  int.width = 0.95, outcome.scale = "response", linearity.check = FALSE,
  robust = FALSE, cluster = NULL, vcov = NULL, set.offset = 1,
  pred.labels = NULL, modx.labels = NULL, mod2.labels = NULL,
  int.type = c("confidence", "prediction"), preds.per.level = 100,
  force.cat = FALSE, facet.modx = linearity.check, ...)
```

Arguments

model	A regression model. The function is tested with <code>lm</code> , <code>glm</code> , <code>svyglm</code> , <code>merMod</code> , <code>rq</code> , <code>brmsfit</code> , <code>stanreg</code> models. Models from other classes may work as well but are not officially supported. The model should include the interaction of interest.
...	Ignored.
pred	The name of the predictor variable involved in the interaction. This must be a string.
predvals	Which values of the predictor should be included in the plot? By default, all levels are included.
modx	The name of the moderator variable involved in the interaction. This must be a string.
modxvals	For which values of the moderator should lines be plotted? Default is <code>NULL</code> . If <code>NULL</code> , then the customary ± 1 standard deviation from the mean as well as the mean itself are used for continuous moderators. If <code>"plus-minus"</code> , plots lines when the moderator is at ± 1 standard deviation without the mean. You may also choose <code>"terciles"</code> to split the data into equally-sized groups and choose the point at the mean of each of those groups. If the moderator is a factor variable and <code>modxvals</code> is <code>NULL</code> , each level of the factor is included. You may specify any subset of the factor levels (e.g., <code>c("Level 1", "Level 3")</code>) as long as there is more than 1. The levels will be plotted in the order you provide them, so this can be used to reorder levels as well.

mod2	Optional. The name of the second moderator variable involved in the interaction. This can be a bare name or string.
mod2vals	For which values of the second moderator should the plot be faceted by? That is, there will be a separate plot for each level of this moderator. Defaults are the same as modxvals.
centered	A vector of quoted variable names that are to be mean-centered. If "all", all non-focal predictors are centered. You may instead pass a character vector of variables to center. User can also use "none" to base all predictions on variables set at 0. The response variable, pred, modx, and mod2 variables are never centered.
data	Optional, default is NULL. You may provide the data used to fit the model. This can be a better way to get mean values for centering and can be crucial for models with variable transformations in the formula (e.g., $\log(x)$) or polynomial terms (e.g., $\text{poly}(x, 2)$). You will see a warning if the function detects problems that would likely be solved by providing the data with this argument and the function will attempt to retrieve the original data from the global environment.
plot.points	Logical. If TRUE, plots the actual data points as a scatterplot on top of the interaction lines. The color of the dots will be based on their moderator value.
interval	Logical. If TRUE, plots confidence/prediction intervals around the line using geom_ribbon .
int.width	How large should the interval be, relative to the standard error? The default, .95, corresponds to roughly 1.96 standard errors and a .05 alpha level for values outside the range. In other words, for a confidence interval, .95 is analogous to a 95% confidence interval.
outcome.scale	For nonlinear models (i.e., GLMs), should the outcome variable be plotted on the link scale (e.g., log odds for logit models) or the original scale (e.g., predicted probabilities for logit models)? The default is "response", which is the original scale. For the link scale, which will show straight lines rather than curves, use "link".
linearity.check	For two-way interactions only. If TRUE, plots a pane for each level of the moderator and superimposes a loess smoothed line (in gray) over the plot. This enables you to see if the effect is linear through the span of the moderator. See Hainmueller et al. (2016) in the references for more details on the intuition behind this. It is recommended that you also set plot.points = TRUE and use modxvals = "terciles" with this option.
robust	Should robust standard errors be used to find confidence intervals for supported models? Default is FALSE, but you should specify the type of sandwich standard errors if you'd like to use them (i.e., "HC0", "HC1", and so on). If TRUE, defaults to "HC3" standard errors.
cluster	For clustered standard errors, provide the column name of the cluster variable in the input data frame (as a string). Alternately, provide a vector of clusters.
vcov	Optional. You may supply the variance-covariance matrix of the coefficients yourself. This is useful if you are using some method for robust standard error calculation not supported by the sandwich package.

set.offset	For models with an offset (e.g., Poisson models), sets an offset for the predicted values. All predicted values will have the same offset. By default, this is set to 1, which makes the predicted values a proportion. See details for more about offset support.
pred.labels	A character vector of 2 labels for the predictor if it is a 2-level factor or a continuous variable with only 2 values. If NULL, the default, the factor labels are used.
modx.labels	A character vector of labels for each level of the moderator values, provided in the same order as the modxvals argument. If NULL, the values themselves are used as labels unless modxvals is also NULL. In that case, "+1 SD" and "-1 SD" are used.
mod2.labels	A character vector of labels for each level of the 2nd moderator values, provided in the same order as the mod2vals argument. If NULL, the values themselves are used as labels unless mod2vals is also NULL. In that case, "+1 SD" and "-1 SD" are used.
int.type	Type of interval to plot. Options are "confidence" or "prediction". Default is confidence interval.
preds.per.level	For continuous predictors, a series of equally spaced points across the observed range of the predictor are used to create the lines for each level of the moderator. Use this to choose how many points are used for that. Default is 100, but for complicated models larger numbers may better capture the curvature.
force.cat	If TRUE, treats numeric predictor as categorical. This can be helpful when you have 0/1 dummy variables that you don't want to plot as if intermediate values are possible.
facet.modx	Create separate panels for each level of the moderator? Default is FALSE, except when linearity.check is TRUE.

make_predictions.brmsfit

Make predictions for brmsfit models

Description

This method adds support for plot_predictions, interact_plot, cat_plot, and effect_plot for models fit with brms.

Usage

```
## S3 method for class 'brmsfit'
make_predictions(model, pred, predvals = NULL,
  modx = NULL, modxvals = NULL, mod2 = NULL, mod2vals = NULL,
  centered = "all", data = NULL, plot.points = FALSE, interval = TRUE,
  int.width = 0.95, estimate = "mean", linearity.check = FALSE,
  set.offset = 1, pred.labels = NULL, modx.labels = NULL,
  mod2.labels = NULL, preds.per.level = 100, force.cat = FALSE,
  facet.modx = linearity.check, ...)
```

Arguments

model	A brmsfit model.
pred	The name of the predictor variable involved in the interaction. This must be a string.
predvals	Which values of the predictor should be included in the plot? By default, all levels are included.
modx	The name of the moderator variable involved in the interaction. This must be a string.
modxvals	For which values of the moderator should lines be plotted? Default is NULL. If NULL, then the customary +/- 1 standard deviation from the mean as well as the mean itself are used for continuous moderators. If "plus-minus", plots lines when the moderator is at +/- 1 standard deviation without the mean. You may also choose "terciles" to split the data into equally-sized groups and choose the point at the mean of each of those groups. If the moderator is a factor variable and modxvals is NULL, each level of the factor is included. You may specify any subset of the factor levels (e.g., c("Level 1", "Level 3")) as long as there is more than 1. The levels will be plotted in the order you provide them, so this can be used to reorder levels as well.
mod2	Optional. The name of the second moderator variable involved in the interaction. This can be a bare name or string.
mod2vals	For which values of the second moderator should the plot be faceted by? That is, there will be a separate plot for each level of this moderator. Defaults are the same as modxvals.
centered	A vector of quoted variable names that are to be mean-centered. If "all", all non-focal predictors are centered. You may instead pass a character vector of variables to center. User can also use "none" to base all predictions on variables set at 0. The response variable, pred, modx, and mod2 variables are never centered.
data	Optional, default is NULL. You may provide the data used to fit the model. This can be a better way to get mean values for centering and can be crucial for models with variable transformations in the formula (e.g., log(x)) or polynomial terms (e.g., poly(x, 2)). You will see a warning if the function detects problems that would likely be solved by providing the data with this argument and the function will attempt to retrieve the original data from the global environment.

plot.points	Logical. If TRUE, plots the actual data points as a scatterplot on top of the interaction lines. The color of the dots will be based on their moderator value.
interval	Logical. If TRUE, plots confidence/prediction intervals around the line using geom_ribbon .
int.width	How large should the interval be, relative to the standard error? The default, .95, corresponds to roughly 1.96 standard errors and a .05 alpha level for values outside the range. In other words, for a confidence interval, .95 is analogous to a 95% confidence interval.
estimate	Should estimates be based on mean or median simulation? Default is "mean".
linearity.check	For two-way interactions only. If TRUE, plots a pane for each level of the moderator and superimposes a loess smoothed line (in gray) over the plot. This enables you to see if the effect is linear through the span of the moderator. See Hainmueller et al. (2016) in the references for more details on the intuition behind this. It is recommended that you also set plot.points = TRUE and use modxvals = "terciles" with this option.
set.offset	For models with an offset (e.g., Poisson models), sets an offset for the predicted values. All predicted values will have the same offset. By default, this is set to 1, which makes the predicted values a proportion. See details for more about offset support.
pred.labels	A character vector of 2 labels for the predictor if it is a 2-level factor or a continuous variable with only 2 values. If NULL, the default, the factor labels are used.
modx.labels	A character vector of labels for each level of the moderator values, provided in the same order as the modxvals argument. If NULL, the values themselves are used as labels unless modxvals is also NULL. In that case, "+1 SD" and "-1 SD" are used.
mod2.labels	A character vector of labels for each level of the 2nd moderator values, provided in the same order as the mod2vals argument. If NULL, the values themselves are used as labels unless mod2vals is also NULL. In that case, "+1 SD" and "-1 SD" are used.
preds.per.level	For continuous predictors, a series of equally spaced points across the observed range of the predictor are used to create the lines for each level of the moderator. Use this to choose how many points are used for that. Default is 100, but for complicated models larger numbers may better capture the curvature.
force.cat	If TRUE, treats numeric predictor as categorical. This can be helpful when you have 0/1 dummy variables that you don't want to plot as if intermediate values are possible.
facet.modx	Create separate panels for each level of the moderator? Default is FALSE, except when linearity.check is TRUE.
...	Ignored.

```
make_predictions.merMod
```

Generate predicted data for merMod models

Description

This function produces predicted data for merMod models, including confidence intervals calculated via one of two methods if requested.

Usage

```
## S3 method for class 'merMod'
make_predictions(model, pred, predvals = NULL, modx = NULL,
  modxvals = NULL, mod2 = NULL, mod2vals = NULL, centered = "all",
  data = NULL, plot.points = FALSE, interval = FALSE, int.width = 0.95,
  outcome.scale = "response", add.re.variance = FALSE,
  linearity.check = FALSE, set.offset = 1, pred.labels = NULL,
  modx.labels = NULL, mod2.labels = NULL, int.type = c("confidence",
  "prediction"), preds.per.level = 100, boot = FALSE, sims = 100,
  progress = "txt", force.cat = FALSE, facet.modx = linearity.check, ...)
```

Arguments

model	A merMod model.
pred	The name of the predictor variable involved in the interaction. This must be a string.
predvals	Which values of the predictor should be included in the plot? By default, all levels are included.
modx	The name of the moderator variable involved in the interaction. This must be a string.
modxvals	For which values of the moderator should lines be plotted? Default is NULL. If NULL, then the customary +/- 1 standard deviation from the mean as well as the mean itself are used for continuous moderators. If "plus-minus", plots lines when the moderator is at +/- 1 standard deviation without the mean. You may also choose "terciles" to split the data into equally-sized groups and choose the point at the mean of each of those groups. If the moderator is a factor variable and modxvals is NULL, each level of the factor is included. You may specify any subset of the factor levels (e.g., c("Level 1", "Level 3")) as long as there is more than 1. The levels will be plotted in the order you provide them, so this can be used to reorder levels as well.
mod2	Optional. The name of the second moderator variable involved in the interaction. This can be a bare name or string.
mod2vals	For which values of the second moderator should the plot be faceted by? That is, there will be a separate plot for each level of this moderator. Defaults are the same as modxvals.

centered	A vector of quoted variable names that are to be mean-centered. If "all", all non-focal predictors are centered. You may instead pass a character vector of variables to center. User can also use "none" to base all predictions on variables set at 0. The response variable, pred, modx, and mod2 variables are never centered.
data	Optional, default is NULL. You may provide the data used to fit the model. This can be a better way to get mean values for centering and can be crucial for models with variable transformations in the formula (e.g., $\log(x)$) or polynomial terms (e.g., $\text{poly}(x, 2)$). You will see a warning if the function detects problems that would likely be solved by providing the data with this argument and the function will attempt to retrieve the original data from the global environment.
plot.points	Logical. If TRUE, plots the actual data points as a scatterplot on top of the interaction lines. The color of the dots will be based on their moderator value.
interval	Logical. If TRUE, plots confidence/prediction intervals around the line using geom_ribbon .
int.width	How large should the interval be, relative to the standard error? The default, .95, corresponds to roughly 1.96 standard errors and a .05 alpha level for values outside the range. In other words, for a confidence interval, .95 is analogous to a 95% confidence interval.
outcome.scale	For nonlinear models (i.e., GLMs), should the outcome variable be plotted on the link scale (e.g., log odds for logit models) or the original scale (e.g., predicted probabilities for logit models)? The default is "response", which is the original scale. For the link scale, which will show straight lines rather than curves, use "link".
add.re.variance	Experimental. Adds variance specific to the <i>random</i> effects in the model. Often overwhelms the fixed effects variances and makes the plot uninterpretable.
linearity.check	For two-way interactions only. If TRUE, plots a pane for each level of the moderator and superimposes a loess smoothed line (in gray) over the plot. This enables you to see if the effect is linear through the span of the moderator. See Hainmueller et al. (2016) in the references for more details on the intuition behind this. It is recommended that you also set <code>plot.points = TRUE</code> and use <code>modxvals = "terciles"</code> with this option.
set.offset	For models with an offset (e.g., Poisson models), sets an offset for the predicted values. All predicted values will have the same offset. By default, this is set to 1, which makes the predicted values a proportion. See details for more about offset support.
pred.labels	A character vector of 2 labels for the predictor if it is a 2-level factor or a continuous variable with only 2 values. If NULL, the default, the factor labels are used.
modx.labels	A character vector of labels for each level of the moderator values, provided in the same order as the <code>modxvals</code> argument. If NULL, the values themselves are used as labels unless <code>modxvals</code> is also NULL. In that case, "+1 SD" and "-1 SD" are used.

mod2.labels	A character vector of labels for each level of the 2nd moderator values, provided in the same order as the mod2vals argument. If NULL, the values themselves are used as labels unless mod2vals is also NULL. In that case, "+1 SD" and "-1 SD" are used.
int.type	Type of interval to plot. Options are "confidence" or "prediction". Default is confidence interval.
preds.per.level	For continuous predictors, a series of equally spaced points across the observed range of the predictor are used to create the lines for each level of the moderator. Use this to choose how many points are used for that. Default is 100, but for complicated models larger numbers may better capture the curvature.
boot	Use <code>lme4::bootMer()</code> to generate confidence intervals instead of estimating fixed effects variance with variance-covariance matrices? Default is FALSE but this is probably more defensible for publication-level output. See Details for a little bit more information.
sims	How many bootstrap simulations should be used? Default is 100, but should usually be much higher. Just be aware that runtime may be considerable.
progress	Should a progress bar be shown during bootstrapping and if so, how should it look? Default is "txt", which is probably what you want to use, but "none" will suppress the progress bar.
force.cat	If TRUE, treats numeric predictor as categorical. This can be helpful when you have 0/1 dummy variables that you don't want to plot as if intermediate values are possible.
facet.modx	Create separate panels for each level of the moderator? Default is FALSE, except when <code>linearity.check</code> is TRUE.
...	Extra arguments passed to <code>lme4::bootMer()</code> if boot is TRUE.

Details

The ability to bootstrap the variances is not available through `interact_plot`, `effect_plot`, and `cat_plot` to keep those functions as simple as possible. Internally, `lme4::bootMer()` is called with with default arguments (`type = "parametric"`, `use.u = FALSE`). To get parallel processing, add the arguments `parallel = "multicore"` or `parallel = "snow"` and `ncpus =` the number of cores.

make_predictions.rq *Make predictions for quantile regression models*

Description

This method adds support for `plot_predictions`, `interact_plot`, `cat_plot`, and `effect_plot` for models fit with `rq`.

Usage

```
## S3 method for class 'rq'
make_predictions(model, pred, predvals = NULL, modx = NULL,
  modxvals = NULL, mod2 = NULL, mod2vals = NULL, centered = "all",
  data = NULL, plot.points = FALSE, int.width = 0.95,
  outcome.scale = "response", linearity.check = FALSE, set.offset = 1,
  pred.labels = NULL, modx.labels = NULL, mod2.labels = NULL,
  int.type = c("confidence", "prediction"), preds.per.level = 100,
  force.cat = FALSE, se = c("nid", "iid", "ker"),
  facet.modx = linearity.check, ...)
```

Arguments

model	A rq model.
pred	The name of the predictor variable involved in the interaction. This must be a string.
predvals	Which values of the predictor should be included in the plot? By default, all levels are included.
modx	The name of the moderator variable involved in the interaction. This must be a string.
modxvals	For which values of the moderator should lines be plotted? Default is NULL. If NULL, then the customary +/- 1 standard deviation from the mean as well as the mean itself are used for continuous moderators. If "plus-minus", plots lines when the moderator is at +/- 1 standard deviation without the mean. You may also choose "terciles" to split the data into equally-sized groups and choose the point at the mean of each of those groups. If the moderator is a factor variable and modxvals is NULL, each level of the factor is included. You may specify any subset of the factor levels (e.g., c("Level 1", "Level 3")) as long as there is more than 1. The levels will be plotted in the order you provide them, so this can be used to reorder levels as well.
mod2	Optional. The name of the second moderator variable involved in the interaction. This can be a bare name or string.
mod2vals	For which values of the second moderator should the plot be faceted by? That is, there will be a separate plot for each level of this moderator. Defaults are the same as modxvals.
centered	A vector of quoted variable names that are to be mean-centered. If "all", all non-focal predictors are centered. You may instead pass a character vector of variables to center. User can also use "none" to base all predictions on variables set at 0. The response variable, pred, modx, and mod2 variables are never centered.
data	Optional, default is NULL. You may provide the data used to fit the model. This can be a better way to get mean values for centering and can be crucial for models with variable transformations in the formula (e.g., log(x)) or polynomial terms (e.g., poly(x, 2)). You will see a warning if the function detects problems that would likely be solved by providing the data with this argument and

	the function will attempt to retrieve the original data from the global environment.
plot.points	Logical. If TRUE, plots the actual data points as a scatterplot on top of the interaction lines. The color of the dots will be based on their moderator value.
int.width	How large should the interval be, relative to the standard error? The default, .95, corresponds to roughly 1.96 standard errors and a .05 alpha level for values outside the range. In other words, for a confidence interval, .95 is analogous to a 95% confidence interval.
outcome.scale	For nonlinear models (i.e., GLMs), should the outcome variable be plotted on the link scale (e.g., log odds for logit models) or the original scale (e.g., predicted probabilities for logit models)? The default is "response", which is the original scale. For the link scale, which will show straight lines rather than curves, use "link".
linearity.check	For two-way interactions only. If TRUE, plots a pane for each level of the moderator and superimposes a loess smoothed line (in gray) over the plot. This enables you to see if the effect is linear through the span of the moderator. See Hainmueller et al. (2016) in the references for more details on the intuition behind this. It is recommended that you also set plot.points = TRUE and use modxvals = "terciles" with this option.
set.offset	For models with an offset (e.g., Poisson models), sets an offset for the predicted values. All predicted values will have the same offset. By default, this is set to 1, which makes the predicted values a proportion. See details for more about offset support.
pred.labels	A character vector of 2 labels for the predictor if it is a 2-level factor or a continuous variable with only 2 values. If NULL, the default, the factor labels are used.
modx.labels	A character vector of labels for each level of the moderator values, provided in the same order as the modxvals argument. If NULL, the values themselves are used as labels unless modxvals is also NULL. In that case, "+1 SD" and "-1 SD" are used.
mod2.labels	A character vector of labels for each level of the 2nd moderator values, provided in the same order as the mod2vals argument. If NULL, the values themselves are used as labels unless mod2vals is also NULL. In that case, "+1 SD" and "-1 SD" are used.
int.type	Type of interval to plot. Options are "confidence" or "prediction". Default is confidence interval.
preds.per.level	For continuous predictors, a series of equally spaced points across the observed range of the predictor are used to create the lines for each level of the moderator. Use this to choose how many points are used for that. Default is 100, but for complicated models larger numbers may better capture the curvature.
force.cat	If TRUE, treats numeric predictor as categorical. This can be helpful when you have 0/1 dummy variables that you don't want to plot as if intermediate values are possible.
se	One of "nid", "iid", "ker", standard error options defined by summary.rq.

facet.modx	Create separate panels for each level of the moderator? Default is FALSE, except when linearity.check is TRUE.
...	Ignored.

make_predictions.stanreg

Make predictions for stanreg models

Description

This method adds support for `plot_predictions`, `interact_plot`, `cat_plot`, and `effect_plot` for models fit with `rstanarm`.

Usage

```
## S3 method for class 'stanreg'
make_predictions(model, pred, predvals = NULL,
  modx = NULL, modxvals = NULL, mod2 = NULL, mod2vals = NULL,
  centered = "all", data = NULL, plot.points = FALSE, interval = TRUE,
  int.width = 0.95, estimate = "mean", linearity.check = FALSE,
  set.offset = 1, pred.labels = NULL, modx.labels = NULL,
  mod2.labels = NULL, preds.per.level = 100, force.cat = FALSE,
  facet.modx = linearity.check, ...)
```

Arguments

model	A stanreg model.
pred	The name of the predictor variable involved in the interaction. This must be a string.
predvals	Which values of the predictor should be included in the plot? By default, all levels are included.
modx	The name of the moderator variable involved in the interaction. This must be a string.
modxvals	For which values of the moderator should lines be plotted? Default is NULL. If NULL, then the customary +/- 1 standard deviation from the mean as well as the mean itself are used for continuous moderators. If "plus-minus", plots lines when the moderator is at +/- 1 standard deviation without the mean. You may also choose "terciles" to split the data into equally-sized groups and choose the point at the mean of each of those groups. If the moderator is a factor variable and modxvals is NULL, each level of the factor is included. You may specify any subset of the factor levels (e.g., c("Level 1", "Level 3")) as long as there is more than 1. The levels will be plotted in the order you provide them, so this can be used to reorder levels as well.
mod2	Optional. The name of the second moderator variable involved in the interaction. This can be a bare name or string.

mod2vals	For which values of the second moderator should the plot be faceted by? That is, there will be a separate plot for each level of this moderator. Defaults are the same as modxvals.
centered	A vector of quoted variable names that are to be mean-centered. If "all", all non-focal predictors are centered. You may instead pass a character vector of variables to center. User can also use "none" to base all predictions on variables set at 0. The response variable, pred, modx, and mod2 variables are never centered.
data	Optional, default is NULL. You may provide the data used to fit the model. This can be a better way to get mean values for centering and can be crucial for models with variable transformations in the formula (e.g., $\log(x)$) or polynomial terms (e.g., $\text{poly}(x, 2)$). You will see a warning if the function detects problems that would likely be solved by providing the data with this argument and the function will attempt to retrieve the original data from the global environment.
plot.points	Logical. If TRUE, plots the actual data points as a scatterplot on top of the interaction lines. The color of the dots will be based on their moderator value.
interval	Logical. If TRUE, plots confidence/prediction intervals around the line using geom_ribbon .
int.width	How large should the interval be, relative to the standard error? The default, .95, corresponds to roughly 1.96 standard errors and a .05 alpha level for values outside the range. In other words, for a confidence interval, .95 is analogous to a 95% confidence interval.
estimate	Should estimates be based on mean or median simulation? Default is "mean".
linearity.check	For two-way interactions only. If TRUE, plots a pane for each level of the moderator and superimposes a loess smoothed line (in gray) over the plot. This enables you to see if the effect is linear through the span of the moderator. See Hainmueller et al. (2016) in the references for more details on the intuition behind this. It is recommended that you also set plot.points = TRUE and use modxvals = "terciles" with this option.
set.offset	For models with an offset (e.g., Poisson models), sets an offset for the predicted values. All predicted values will have the same offset. By default, this is set to 1, which makes the predicted values a proportion. See details for more about offset support.
pred.labels	A character vector of 2 labels for the predictor if it is a 2-level factor or a continuous variable with only 2 values. If NULL, the default, the factor labels are used.
modx.labels	A character vector of labels for each level of the moderator values, provided in the same order as the modxvals argument. If NULL, the values themselves are used as labels unless modxvals is also NULL. In that case, "+1 SD" and "-1 SD" are used.
mod2.labels	A character vector of labels for each level of the 2nd moderator values, provided in the same order as the mod2vals argument. If NULL, the values themselves are used as labels unless mod2vals is also NULL. In that case, "+1 SD" and "-1 SD" are used.

preds.per.level	For continuous predictors, a series of equally spaced points across the observed range of the predictor are used to create the lines for each level of the moderator. Use this to choose how many points are used for that. Default is 100, but for complicated models larger numbers may better capture the curvature.
force.cat	If TRUE, treats numeric predictor as categorical. This can be helpful when you have 0/1 dummy variables that you don't want to plot as if intermediate values are possible.
facet.modx	Create separate panels for each level of the moderator? Default is FALSE, except when linearity.check is TRUE.
...	Ignored.

pf_sv_test	<i>Test whether sampling weights are needed</i>
------------	---

Description

Use the test proposed in Pfeffermann and Sverchkov (1999) to check whether a regression model is specified correctly without weights.

Usage

```
pf_sv_test(model, data = NULL, weights, sims = 1000,
           digits = getOption("jtools-digits", default = 3))
```

Arguments

model	The fitted model, without weights
data	The data frame with the data fed to the fitted model and the weights
weights	The name of the weights column in model's data frame or a vector of weights equal in length to the number of observations included in model.
sims	The number of bootstrap simulations to use in estimating the variance of the residual correlation. Default is 1000, but for publications or when computing power/time is sufficient, a higher number is better.
digits	An integer specifying the number of digits past the decimal to report in the output. Default is 3. You can change the default number of digits for all jtools functions with <code>options("jtools-digits" = digits)</code> where <code>digits</code> is the desired number.

Details

This is a test described by Pfeffermann and Sverchkov (1999) that is designed to help analysts decide whether they need to use sample weights in their regressions to avoid biased parameter estimation.

It first checks the correlation of the residuals of the model with the weights. It then uses bootstrapping to estimate the variance of the correlation, ending with a t-test of whether the correlation differs from zero. This is done for the squared residuals and cubed residuals as well. If anyone of them are statistically significant (at whatever level you feel appropriate), it is best to do a weighted regression. Note that in large samples, a very small correlation may have a low p-value without a large bias in the unweighted regression.

Examples

```
# Note: This is a contrived example to show how the function works,
# not a case with actual sampling weights from a survey vendor
if (requireNamespace("boot")) {
  states <- as.data.frame(state.x77)
  set.seed(100)
  states$wts <- runif(50, 0, 3)
  fit <- lm(Murder ~ Illiteracy + Frost, data = states)
  pf_sv_test(model = fit, data = states, weights = wts, sims = 100)
}
```

plot_predictions

Plot predicted effects from make_predictions

Description

The companion function to [make_predictions\(\)](#). This takes data from [make_predictions\(\)](#) (or elsewhere) and plots them like [effect_plot\(\)](#), [interact_plot\(\)](#), and [cat_plot\(\)](#). Note that some arguments will be ignored if the inputted predictions

Usage

```
plot_predictions(predictions, pred = NULL, modx = NULL, mod2 = NULL,
  resp = NULL, data = NULL, geom = c("point", "line", "bar", "boxplot"),
  plot.points = FALSE, interval = TRUE, predvals = NULL,
  modxvals = NULL, mod2vals = NULL, linearity.check = FALSE,
  facet.modx = FALSE, x.label = NULL, y.label = NULL,
  pred.labels = NULL, modx.labels = NULL, mod2.labels = NULL,
  main.title = NULL, legend.main = NULL, color.class = NULL,
```

```

line.thickness = 1.1, vary.lty = NULL, jitter = 0, weights = NULL,
rug = FALSE, rug.sides = "b", force.cat = FALSE, point.shape = FALSE,
geom.alpha = NULL, dodge.width = NULL, errorbar.width = NULL,
interval.geom = c("errorbar", "linrange"), pred.point.size = 3.5,
point.size = 1, ...)

```

Arguments

predictions	Either the output from <code>make_predictions()</code> (an object of class "predictions") or a data frame of predicted values.
pred	The name of the predictor variable involved in the interaction. This can be a bare name or string.
modx	The name of the moderator variable involved in the interaction. This can be a bare name or string.
mod2	Optional. The name of the second moderator variable involved in the interaction. This can be a bare name or string.
resp	What is the name of the response variable? Use a string.
data	Optional, default is NULL. You may provide the data used to fit the model. This can be a better way to get mean values for centering and can be crucial for models with variable transformations in the formula (e.g., $\log(x)$) or polynomial terms (e.g., $\text{poly}(x, 2)$). You will see a warning if the function detects problems that would likely be solved by providing the data with this argument and the function will attempt to retrieve the original data from the global environment.
geom	<p>For factor predictors only: What type of plot should this be? There are several options here since the best way to visualize categorical interactions varies by context. Here are the options:</p> <ul style="list-style-type: none"> • "point": The default. Simply plot the point estimates. You may want to use <code>point.shape = TRUE</code> with this and you should also consider <code>interval = TRUE</code> to visualize uncertainty. • "line": This connects observations across levels of the pred variable with a line. This is a good option when the pred variable is ordinal (ordered). You may still consider <code>point.shape = TRUE</code> and <code>interval = TRUE</code> is still a good idea. • "bar": A bar chart. Some call this a "dynamite plot." Many applied researchers advise against this type of plot because it does not represent the distribution of the observed data or the uncertainty of the predictions very well. It is best to at least use the <code>interval = TRUE</code> argument with this geom. • "boxplot": This geom plots a dot and whisker plot. These can be useful for understanding the distribution of the observed data without having to plot all the observed points (especially helpful with larger data sets). However, it is important to note the boxplots are not based on the model whatsoever.
plot.points	Logical. If TRUE, plots the actual data points as a scatterplot on top of the interaction lines. The color of the dots will be based on their moderator value.

interval	Logical. If TRUE, plots confidence/prediction intervals around the line using <code>geom_ribbon</code> .
predvals	Which values of the predictor should be included in the plot? By default, all levels are included.
modxvals	For which values of the moderator should lines be plotted? Default is NULL. If NULL, then the customary +/- 1 standard deviation from the mean as well as the mean itself are used for continuous moderators. If "plus-minus", plots lines when the moderator is at +/- 1 standard deviation without the mean. You may also choose "terciles" to split the data into equally-sized groups and choose the point at the mean of each of those groups. If the moderator is a factor variable and <code>modxvals</code> is NULL, each level of the factor is included. You may specify any subset of the factor levels (e.g., <code>c("Level 1", "Level 3")</code>) as long as there is more than 1. The levels will be plotted in the order you provide them, so this can be used to reorder levels as well.
mod2vals	For which values of the second moderator should the plot be faceted by? That is, there will be a separate plot for each level of this moderator. Defaults are the same as <code>modxvals</code> .
linearity.check	For two-way interactions only. If TRUE, plots a pane for each level of the moderator and superimposes a loess smoothed line (in gray) over the plot. This enables you to see if the effect is linear through the span of the moderator. See Hainmueller et al. (2016) in the references for more details on the intuition behind this. It is recommended that you also set <code>plot.points = TRUE</code> and use <code>modxvals = "terciles"</code> with this option.
facet.modx	Create separate panels for each level of the moderator? Default is FALSE, except when <code>linearity.check</code> is TRUE.
x.label	A character object specifying the desired x-axis label. If NULL, the variable name is used.
y.label	A character object specifying the desired y-axis label. If NULL, the variable name is used.
pred.labels	A character vector of 2 labels for the predictor if it is a 2-level factor or a continuous variable with only 2 values. If NULL, the default, the factor labels are used.
modx.labels	A character vector of labels for each level of the moderator values, provided in the same order as the <code>modxvals</code> argument. If NULL, the values themselves are used as labels unless <code>modxvals</code> is also NULL. In that case, "+1 SD" and "-1 SD" are used.
mod2.labels	A character vector of labels for each level of the 2nd moderator values, provided in the same order as the <code>mod2vals</code> argument. If NULL, the values themselves are used as labels unless <code>mod2vals</code> is also NULL. In that case, "+1 SD" and "-1 SD" are used.
main.title	A character object that will be used as an overall title for the plot. If NULL, no main title is used.
legend.main	A character object that will be used as the title that appears above the legend. If NULL, the name of the moderating variable is used.

color.class	See jtools_colors for details on the types of arguments accepted. Default is "CUD Bright" for factor moderators, "Blues" for +/- SD and user-specified modxvals values.
line.thickness	How thick should the plotted lines be? Default is 1.1; ggplot's default is 1.
vary.lty	Should the resulting plot have different shapes for each line in addition to colors? Default is NULL, which will switch to FALSE if the pred is a factor and TRUE if pred is continuous.
jitter	How much should plot.points observed values be "jittered" via ggplot2::position_jitter() ? When there are many points near each other, jittering moves them a small amount to keep them from totally overlapping. In some cases, though, it can add confusion since it may make points appear to be outside the boundaries of observed values or cause other visual issues. Default is 0, but try various small values (e.g., 0.1) and increase as needed if your points are overlapping too much. If the argument is a vector with two values, then the first is assumed to be the jitter for width and the second for the height.
weights	If the data are weighted, provide a vector of weights here. This is only used if plot.points = TRUE and data is not NULL.
rug	Show a rug plot in the margins? This uses ggplot2::geom_rug() to show the distribution of the predictor (top/bottom) and/or response variable (left/right) in the original data. Default is FALSE.
rug.sides	On which sides should rug plots appear? Default is "b", meaning bottom. "t" and/or "b" show the distribution of the predictor while "l" and/or "r" show the distribution of the response. "bl" is a good option to show both the predictor and response.
force.cat	Force the predictor to be treated as if it is a factor, even if it isn't? Default is FALSE. Set to TRUE if you'd like to generate a type of plot normally reserved for categorical variables. This can be helpful for numeric variables that have a small number of unique values, for instance.
point.shape	For plotted points—either of observed data or predicted values with the "point" or "line" geoms—should the shape of the points vary by the values of the factor? This is especially useful if you aim to be black and white printing- or colorblind-friendly.
geom.alpha	What should the alpha aesthetic be for the plotted lines/bars? Default is NULL, which means it is set depending on the value of geom and plot.points.
dodge.width	What should the width argument to ggplot2::position_dodge() be? Default is NULL, which means it is set depending on the value of geom.
errorbar.width	How wide should the error bars be? Default is NULL, meaning it is set depending on the value geom. Ignored if interval is FALSE.
interval.geom	For categorical by categorical interactions. One of "errorbar" or "linerange". If the former, ggplot2::geom_errorbar() is used. If the latter, ggplot2::geom_linerange() is used.
pred.point.size	If TRUE and geom is "point" or "line", sets the size of the predicted points. Default is 3.5. Note the distinction from point.size, which refers to the observed data points.

point.size	What size should be used for observed data when plot.points is TRUE? Default is 2.
...	Ignored.

Details

This is designed to offer more flexibility than the canned functions ([effect_plot\(\)](#), [interact_plot\(\)](#), and [cat_plot\(\)](#)), by letting you generate your own predicted data and iteratively experiment with the plotting options.

Note: predictions objects from [make_predictions\(\)](#) store information about the arguments used to create the object. Unless you specify those arguments manually to this function, as a convenience `plot_predictions` will use the arguments stored in the predictions object. Those arguments are:

- pred, modx, and mod2
- resp
- predvals, modxvals, and mod2vals
- pred.labels, modx.labels, and mod2.labels
- data
- interval
- linearity.check
- weights

plot_summs

Plot Regression Summaries

Description

`plot_summs` and `plot_coefs` create regression coefficient plots with `ggplot2`.

Usage

```
plot_summs(..., ci_level = 0.95, model.names = NULL, coefs = NULL,
  omit.coefs = "(Intercept)", inner_ci_level = NULL,
  color.class = "CUD Bright", plot.distributions = FALSE,
  rescale.distributions = FALSE, exp = FALSE, point.shape = TRUE,
  legend.title = "Model")
```

```
plot_coefs(..., ci_level = 0.95, inner_ci_level = NULL,
  model.names = NULL, coefs = NULL, omit.coefs = c("(Intercept)",
  "Intercept"), color.class = "CUD Bright", plot.distributions = FALSE,
  rescale.distributions = FALSE, exp = FALSE, point.shape = TRUE,
  legend.title = "Model")
```

Arguments

...	regression model(s).
ci_level	The desired width of confidence intervals for the coefficients. Default: 0.95
model.names	If plotting multiple models simultaneously, you can provide a vector of names here. If NULL, they will be named sequentially as "Model 1", "Model 2", and so on. Default: NULL
coefs	If you'd like to include only certain coefficients, provide them as a vector. If it is a named vector, then the names will be used in place of the variable names. See details for examples. Default: NULL
omit.coefs	If you'd like to specify some coefficients to not include in the plot, provide them as a vector. This argument is overridden by coefs if both are provided. By default, the intercept term is omitted. To include the intercept term, just set omit.coefs to NULL.
inner_ci_level	Plot a thicker line representing some narrower span than ci_level. Default is NULL, but good options are .9, .8, or .5.
color.class	See jtools_colors for more on your color options. Default: 'CUD Bright'
plot.distributions	Instead of just plotting the ranges, you may plot normal distributions representing the width of each estimate. Note that these are completely theoretical and not based on a bootstrapping or MCMC procedure, even if the source model was fit that way. Default is FALSE.
rescale.distributions	If plot.distributions is TRUE, the default behavior is to plot each normal density curve on the same scale. If some of the uncertainty intervals are much wider/narrower than others, that means the wide ones will have such a low height that you won't be able to see the curve. If you set this parameter to TRUE, each curve will have the same maximum height regardless of their width.
exp	If TRUE, all coefficients are exponentiated (e.g., transforms logit coefficients from log odds scale to odds). The reference line is also moved to 1 instead of 0.
point.shape	When using multiple models, should each model's point estimates use a different point shape to visually differentiate each model from the others? Default is TRUE.
legend.title	What should the title for the legend be? Default is "Model", but you can specify it here since it is rather difficult to change later via ggplot2's typical methods.

Details

A note on the distinction between `plot_summs` and `plot_coefs`: `plot_summs` only accepts models supported by `summ()` and allows users to take advantage of the standardization and robust standard error features (among others as may be relevant). `plot_coefs` supports any models that have a `broom::tidy()` method defined in the broom package, but of course lacks any additional features like robust standard errors. To get a mix of the two, you can pass `summ` objects to `plot_coefs` too.

For `coefs`, if you provide a named vector of coefficients, then the plot will refer to the selected coefficients by the names of the vector rather than the coefficient names. For instance, if I want to include only the coefficients for the `hp` and `mpg` but have the plot refer to them as "Horsepower" and "Miles/gallon", I'd provide the argument like this: `c("Horsepower" = "hp", "Miles/gallon" = "mpg")`

Value

A ggplot object.

Examples

```
states <- as.data.frame(state.x77)
fit1 <- lm(Income ~ Frost + Illiteracy + Murder +
           Population + Area + `Life Exp` + `HS Grad`,
           data = states, weights = runif(50, 0.1, 3))
fit2 <- lm(Income ~ Frost + Illiteracy + Murder +
           Population + Area + `Life Exp` + `HS Grad`,
           data = states, weights = runif(50, 0.1, 3))
fit3 <- lm(Income ~ Frost + Illiteracy + Murder +
           Population + Area + `Life Exp` + `HS Grad`,
           data = states, weights = runif(50, 0.1, 3))

# Plot all 3 regressions with custom predictor labels,
# standardized coefficients, and robust standard errors
plot_summs(fit1, fit2, fit3,
           coefs = c("Frost Days" = "Frost", "% Illiterate" = "Illiteracy",
                    "Murder Rate" = "Murder"),
           scale = TRUE, robust = TRUE)
```

probe_interaction *Probe interaction effects via simple slopes and plotting*

Description

probe_interaction is a convenience function that allows users to call both [sim_slopes](#) and [interact_plot](#) with a single call.

Usage

```
probe_interaction(model, pred, modx, mod2 = NULL, ...)
```

Arguments

model	A regression model of type <code>lm</code> or <code>svyglm</code> . It should contain the interaction of interest.
pred	The predictor variable involved in the interaction.
modx	The moderator variable involved in the interaction.
mod2	Optional. The name of the second moderator variable involved in the interaction.
...	Other arguments accepted by sim_slopes and interact_plot

Details

This function simply merges the nearly-equivalent arguments needed to call both [sim_slopes](#) and [interact_plot](#) without the need for re-typing their common arguments. Note that each function is called separately and they re-fit a separate model for each level of each moderator; therefore, the runtime may be considerably longer than the original model fit. For larger models, this is worth keeping in mind.

Sometimes, you may want different parameters when doing simple slopes analysis compared to when plotting interaction effects. For instance, it is often easier to interpret the regression output when variables are standardized; but plots are often easier to understand when the variables are in their original units of measure.

`probe_interaction` does not support providing different arguments to each function. If that is needed, use `sim_slopes` and `interact_plot` directly.

Value

<code>simslopes</code>	The <code>sim_slopes</code> object created.
<code>interactplot</code>	The <code>ggplot</code> object created by <code>interact_plot</code> .

probe_interaction(model = regmodel3, pred = ell, modx = sch.wide,
                 mod2 = meals)
}

```

scale_mod

Scale variables in fitted regression models

Description

scale_mod (previously known as scale_lm) takes fitted regression models and scales all predictors by dividing each by 1 or 2 standard deviations (as chosen by the user).

Usage

```

scale_mod(model, ...)

## Default S3 method:
scale_mod(model, binary.inputs = "0/1", n.sd = 1,
          center = TRUE, scale.response = FALSE, center.only = FALSE,
          data = NULL, vars = NULL,
          apply.weighted.contrasts = getOption("jtools-weighted.contrasts", FALSE),
          ...)

```

Arguments

model	A regression model of type <code>lm</code> , <code>glm</code> , <code>svyglm</code> , or <code>lme4::merMod</code> . Other model types may work as well but are not tested.
...	Ignored.
binary.inputs	Options for binary variables. Default is "0/1"; "0/1" keeps original scale; "-0.5,0.5" rescales 0 as -0.5 and 1 as 0.5; center subtracts the mean; and full treats them like other continuous variables.
n.sd	How many standard deviations should you divide by for standardization? Default is 1, though some prefer 2.
center	Default is TRUE. If TRUE, the predictors are also mean-centered. For binary predictors, the binary.inputs argument supersedes this one.
scale.response	Should the response variable also be rescaled? Default is FALSE.
center.only	Rather than actually scale predictors, just mean-center them.
data	If you provide the data used to fit the model here, that data frame is used to re-fit the model instead of the <code>stats::model.frame()</code> of the model. This is particularly useful if you have variable transformations or polynomial terms specified in the formula.

`vars` A character vector of variable names that you want to be scaled. If NULL, the default, it is all predictors.

`apply.weighted.contrasts` Factor variables cannot be scaled, but you can set the contrasts such that the intercept in a regression model will reflect the true mean (assuming all other variables are centered). If set to TRUE, the argument will apply weighted effects coding to all factors. This is similar to the R default effects coding, but weights according to how many observations are at each level. An adapted version of `wec::contr.wec()` from the `wec` package is used to do this. See that package's documentation and/or Grotenhuis et al. (2016) for more info.

Details

This function will scale all continuous variables in a regression model for ease of interpretation, especially for those models that have interaction terms. It can also mean-center all of them as well, if requested.

The scaling happens on the input data, not the terms themselves. That means interaction terms are still properly calculated because they are the product of standardized predictors, not a standardized product of predictors.

This function re-estimates the model, so for large models one should expect a runtime equal to the first run.

Value

The functions returns a re-fitted model object, inheriting from whichever class was supplied.

fit <- lm(formula = Murder ~ Income * Illiteracy,
          data = as.data.frame(state.x77))
fit_scale <- scale_mod(fit)
fit_scale <- scale_mod(fit, center = TRUE)

# With weights
fitw <- lm(formula = Murder ~ Income * Illiteracy,
           data = as.data.frame(state.x77),
           weights = Population)
fitw_scale <- scale_mod(fitw)
fitw_scale <- scale_mod(fitw, center = TRUE, binary.input = "0/1")

# With svyglm
if (requireNamespace("survey")) {
  library(survey)
  data(api)
  dstrat<-svydesign(id=~1,strata=~stype, weights=~pw, data=apistrat, fpc=~fpc)
  regmodel <- svyglm(api00~ell*meals,design=dstrat)
  regmodel_scale <- scale_mod(regmodel)
  regmodel_scale <- scale_mod(regmodel, binary.input = "0/1")
}

```

set_summ_defaults *Set defaults for summ function*

Description

This function is convenience wrapper for manually setting options using `options()`. This gives a handy way to, for instance, set the arguments to be used in every call to `summ` in your script/session.

To make the settings persist across sessions, you can run this in your `.Rprofile` file.

Note that arguments that do not apply (e.g., `robust` for `merMod` models) are silently ignored when those types of models are used.

Usage

```

set_summ_defaults(digits = NULL, model.info = NULL, model.fit = NULL,
                  pvals = NULL, robust = NULL, confint = NULL, ci.width = NULL,
                  vifs = NULL, conf.method = NULL)

```

Arguments

`digits` An integer specifying the number of digits past the decimal to report in the output. Default is 2. You can change the default number of digits for all `jtools` functions with `options("jtools-digits" = digits)` where `digits` is the desired number.

model.info	Toggles printing of basic information on sample size, name of DV, and number of predictors.
model.fit	Toggles printing of model fit statistics.
pvals	Show p values and significance stars? If FALSE, these are not printed. Default is TRUE.
robust	If not FALSE, reports heteroskedasticity-robust standard errors instead of conventional SEs. These are also known as Huber-White standard errors. There are several options provided by <code>sandwich::vcovHC()</code> : "HC0", "HC1", "HC2", "HC3", "HC4", "HC4m", "HC5". Default is FALSE. This requires the <code>sandwich</code> package to compute the standard errors.
confint	Show confidence intervals instead of standard errors? Default is FALSE.
ci.width	A number between 0 and 1 that signifies the width of the desired confidence interval. Default is .95, which corresponds to a 95% confidence interval. Ignored if <code>confint = FALSE</code> .
vifs	If TRUE, adds a column to output with variance inflation factors (VIF). Default is FALSE.
conf.method	Argument passed to <code>lme4::confint.merMod()</code> . Default is "Wald", but "profile" or "boot" are better when accuracy is a priority. Be aware that both of the alternate methods are sometimes very time-consuming.

sim_slopes	<i>Perform a simple slopes analysis.</i>
------------	--

Description

`sim_slopes` conducts a simple slopes analysis for the purposes of understanding two- and three-way interaction effects in linear regression.

Usage

```
sim_slopes(model, pred, modx, mod2 = NULL, modxvals = NULL,
  mod2vals = NULL, centered = "all", data = NULL, cond.int = FALSE,
  johnson_neyman = TRUE, jnplot = FALSE, jnalpha = 0.05, robust = FALSE,
  digits = getOption("jtools-digits", default = 2), pvals = TRUE,
  confint = FALSE, ci.width = 0.95, cluster = NULL, ...)
```

Arguments

model	A regression model. The function is tested with <code>lm</code> , <code>glm</code> , <code>svyglm</code> , <code>merMod</code> , <code>rq</code> , <code>brmsfit</code> , <code>stanreg</code> models. Models from other classes may work as well but are not officially supported. The model should include the interaction of interest.
pred	The predictor variable involved in the interaction.
modx	The moderator variable involved in the interaction.

mod2	Optional. The name of the second moderator variable involved in the interaction.
modxvals	For which values of the moderator should simple slopes analysis be performed? Default is NULL. If NULL, then the values will be the customary +/- 1 standard deviation from the mean as well as the mean itself. There is no specific limit on the number of variables provided. If "plus-minus", uses just +/- 1 standard deviation without the mean. You may also choose "terciles" to split the data into equally-sized groups and choose the point at the mean of each of those groups. Factor variables are not particularly suited to simple slopes analysis, but you could have a numeric moderator with values of 0 and 1 and give $c(0, 1)$ to compare the slopes at the different conditions. Two-level factor variables are coerced to numeric 0/1 variables, but are not standardized/centered like they could be if your input data had a numeric 0/1 variable.
mod2vals	For which values of the second moderator should the plot be faceted by? That is, there will be a separate plot for each level of this moderator. Defaults are the same as modxvals.
centered	A vector of quoted variable names that are to be mean-centered. If "all", all non-focal predictors as well as the pred variable are centered. You may instead pass a character vector of variables to center. User can also use "none" to base all predictions on variables set at 0. The response variable, modx, and mod2 variables are never centered.
data	Optional, default is NULL. You may provide the data used to fit the model. This can be a better way to get mean values for centering and can be crucial for models with variable transformations in the formula (e.g., $\log(x)$) or polynomial terms (e.g., $\text{poly}(x, 2)$). You will see a warning if the function detects problems that would likely be solved by providing the data with this argument and the function will attempt to retrieve the original data from the global environment.
cond.int	Should conditional intercepts be printed in addition to the slopes? Default is FALSE.
johnson_neyman	Should the Johnson-Neyman interval be calculated? Default is TRUE. This can be performed separately with johnson_neyman .
jnplot	Should the Johnson-Neyman interval be plotted as well? Default is FALSE.
jnalp	What should the alpha level be for the Johnson-Neyman interval? Default is .05, which corresponds to a 95% confidence interval.
robust	Should robust standard errors be used to find confidence intervals for supported models? Default is FALSE, but you should specify the type of sandwich standard errors if you'd like to use them (i.e., "HC0", "HC1", and so on). If TRUE, defaults to "HC3" standard errors.
digits	An integer specifying the number of digits past the decimal to report in the output. Default is 2. You can change the default number of digits for all jtools functions with <code>options("jtools-digits" = digits)</code> where digits is the desired number.
pvals	Show p values and significance stars? If FALSE, these are not printed. Default is TRUE.

confint	Show confidence intervals instead of standard errors? Default is FALSE.
ci.width	A number between 0 and 1 that signifies the width of the desired confidence interval. Default is .95, which corresponds to a 95% confidence interval. Ignored if confint = FALSE.
cluster	For clustered standard errors, provide the column name of the cluster variable in the input data frame (as a string). Alternately, provide a vector of clusters.
...	Arguments passed to johnson_neyman and <code>summ</code> .

Details

This allows the user to perform a simple slopes analysis for the purpose of probing interaction effects in a linear regression. Two- and three-way interactions are supported, though one should be warned that three-way interactions are not easy to interpret in this way.

For more about Johnson-Neyman intervals, see [johnson_neyman](#).

The function is tested with `lm`, `glm`, `svyglm`, and `merMod` inputs. Others may work as well, but are not tested. In all but the linear model case, be aware that not all the assumptions applied to simple slopes analysis apply.

Value

slopes	A table of coefficients for the focal predictor at each value of the moderator
ints	A table of coefficients for the intercept at each value of the moderator
modxvals	The values of the moderator used in the analysis
mods	A list containing each regression model created to estimate the conditional coefficients.
jn	If <code>johnson_neyman = TRUE</code> , a list of <code>johnson_neyman</code> objects from johnson_neyman . These contain the values of the interval and the plots. If a 2-way interaction, the list will be of length <ol style="list-style-type: none"> 1. Otherwise, there will be 1 <code>johnson_neyman</code> object for each value of the 2nd moderator for 3-way interactions.

Examples

```
# Using a fitted model as formula input
fiti <- lm(Income ~ Frost + Murder * Illiteracy,
  data = as.data.frame(state.x77))
sim_slopes(model = fiti, pred = Murder, modx = Illiteracy)

# With svyglm
if (requireNamespace("survey")) {
  library(survey)
  data(api)
  dstrat <- svydesign(id = ~1, strata = ~stype, weights = ~pw,
    data = apistrat, fpc = ~fpc)
  regmodel <- svyglm(api00 ~ ell * meals, design = dstrat)
  sim_slopes(regmodel, pred = ell, modx = meals)

# 3-way with survey and factor input
regmodel <- svyglm(api00 ~ ell * meals * sch.wide, design = dstrat)
sim_slopes(regmodel, pred = ell, modx = meals, mod2 = sch.wide)
}
```

 standardize

Standardize vectors, data frames, and survey designs

Description

This function is a wrapper around [gscale\(\)](#) that is configured to do a conventional standardization of continuous variables, mean-centering and dividing by one standard deviation.

Usage

```
standardize(data = NULL, vars = NULL, binary.inputs = "center",
  binary.factors = TRUE, weights = NULL)
```

Arguments

data A data frame or survey design. Only needed if you would like to rescale multiple variables at once. If `x = NULL`, all columns will be rescaled. Otherwise, `x` should be a vector of variable names. If `x` is a numeric vector, this argument is ignored.

<code>vars</code>	If data is a <code>data.frame</code> or similar, you can scale only select columns by providing a vector column names to this argument.
<code>binary.inputs</code>	Options for binary variables. Default is <code>center</code> ; <code>0/1</code> keeps original scale; <code>-0.5/0.5</code> rescales 0 as -0.5 and 1 as 0.5; <code>center</code> subtracts the mean; and <code>full</code> subtracts the mean and divides by 2 sd.
<code>binary.factors</code>	Coerce two-level factors to numeric and apply scaling functions to them? Default is <code>TRUE</code> .
<code>weights</code>	A vector of weights equal in length to <code>x</code> . If iterating over a data frame, the weights will need to be equal in length to all the columns to avoid errors. You may need to remove missing values before using the weights.

Details

Some more information can be found in the documentation for [gscale\(\)](#)

Value

A transformed version of the data argument.

 summ.glm

Generalized linear regression summaries with options

Description

summ prints output for a regression model in a fashion similar to summary, but formatted differently with more options.

Usage

```
## S3 method for class 'glm'
summ(model, scale = FALSE, confint = getOption("summ-confint",
  FALSE), ci.width = getOption("summ-ci.width", 0.95),
  robust = getOption("summ-robust", FALSE), cluster = NULL,
  vifs = getOption("summ-vifs", FALSE), digits = getOption("jtools-digits",
  default = 2), exp = FALSE, pvals = getOption("summ-pvals", TRUE),
  n.sd = 1, center = FALSE, transform.response = FALSE, data = NULL,
  model.info = getOption("summ-model.info", TRUE),
  model.fit = getOption("summ-model.fit", TRUE), which.cols = NULL, ...)
```

Arguments

model	A glm object.
scale	If TRUE, reports standardized regression coefficients. Default is FALSE.
confint	Show confidence intervals instead of standard errors? Default is FALSE.
ci.width	A number between 0 and 1 that signifies the width of the desired confidence interval. Default is .95, which corresponds to a 95% confidence interval. Ignored if confint = FALSE.
robust	If not FALSE, reports heteroskedasticity-robust standard errors instead of conventional SEs. These are also known as Huber-White standard errors. There are several options provided by <code>sandwich::vcovHC()</code> : "HC0", "HC1", "HC2", "HC3", "HC4", "HC4m", "HC5". Default is FALSE. This requires the sandwich package to compute the standard errors.
cluster	For clustered standard errors, provide the column name of the cluster variable in the input data frame (as a string). Alternately, provide a vector of clusters.

vifs	If TRUE, adds a column to output with variance inflation factors (VIF). Default is FALSE.
digits	An integer specifying the number of digits past the decimal to report in the output. Default is 2. You can change the default number of digits for all jtools functions with <code>options("jtools-digits" = digits)</code> where <code>digits</code> is the desired number.
exp	If TRUE, reports exponentiated coefficients with confidence intervals for exponential models like logit and Poisson models. This quantity is known as an odds ratio for binary outcomes and incidence rate ratio for count models.
pvals	Show p values and significance stars? If FALSE, these are not printed. Default is TRUE.
n.sd	If <code>scale = TRUE</code> , how many standard deviations should predictors be divided by? Default is 1, though some suggest 2.
center	If you want coefficients for mean-centered variables but don't want to standardize, set this to TRUE.
transform.response	Should scaling/centering apply to response variable? Default is FALSE.
data	If you provide the data used to fit the model here, that data frame is used to re-fit the model (if <code>scale</code> is TRUE) instead of the <code>stats::model.frame()</code> of the model. This is particularly useful if you have variable transformations or polynomial terms specified in the formula.
model.info	Toggles printing of basic information on sample size, name of DV, and number of predictors.
model.fit	Toggles printing of model fit statistics.
which.cols	Developmental feature. By providing columns by name, you can add/remove/reorder requested columns in the output. Not fully supported, for now.
...	This just captures extra arguments that may only work for other types of models.

Details

By default, this function will print the following items to the console:

- The sample size
- The name of the outcome variable
- The chi-squared test, (Pseudo-)R-squared value and AIC/BIC.
- A table with regression coefficients, standard errors, z values, and p values.

There are several options available for `robust`. The heavy lifting is done by `vcovHC`, where those are better described. Put simply, you may choose from "HC0" to "HC5". Based on the recommendation of the developers of **sandwich**, the default is set to "HC3". Stata's default is "HC1", so that choice may be better if the goal is to replicate Stata's output. Any option that is understood by `vcovHC` will be accepted. Cluster-robust standard errors are computed if `cluster` is set to the name of the input data's cluster variable or is a vector of clusters.

The `scale` and `center` options are performed via refitting the model with `scale_mod` and `center_mod`, respectively. Each of those in turn uses `gscale` for the mean-centering and scaling.

Value

If saved, users can access most of the items that are returned in the output (and without rounding).

coeftable	The outputted table of variables and coefficients
model	The model for which statistics are displayed. This would be most useful in cases in which <code>scale = TRUE</code> .

Much other information can be accessed as attributes.

<code>data</code>	If you provide the data used to fit the model here, that data frame is used to re-fit the model (if <code>scale</code> is <code>TRUE</code>) instead of the <code>stats::model.frame()</code> of the model. This is particularly useful if you have variable transformations or polynomial terms specified in the formula.
<code>part.corr</code>	Print partial (labeled "partial.r") and semipartial (labeled "part.r") correlations with the table? Default is <code>FALSE</code> . See details about these quantities when robust standard errors are used.
<code>model.info</code>	Toggles printing of basic information on sample size, name of DV, and number of predictors.
<code>model.fit</code>	Toggles printing of model fit statistics.
<code>model.check</code>	Toggles whether to perform Breusch-Pagan test for heteroskedasticity and print number of high-leverage observations. See details for more info.
<code>which.cols</code>	Developmental feature. By providing columns by name, you can add/remove/reorder requested columns in the output. Not fully supported, for now.
<code>...</code>	This just captures extra arguments that may only work for other types of models.

Details

By default, this function will print the following items to the console:

- The sample size
- The name of the outcome variable
- The R-squared value plus adjusted R-squared
- A table with regression coefficients, standard errors, t-values, and p values.

There are several options available for `robust`. The heavy lifting is done by `vcovHC`, where those are better described. Put simply, you may choose from "HC0" to "HC5". Based on the recommendation of the developers of **sandwich**, the default is set to "HC3". Stata's default is "HC1", so that choice may be better if the goal is to replicate Stata's output. Any option that is understood by `vcovHC` will be accepted. Cluster-robust standard errors are computed if `cluster` is set to the name of the input data's cluster variable or is a vector of clusters.

The `scale` and `center` options are performed via refitting the model with `scale_mod` and `center_mod`, respectively. Each of those in turn uses `gscale` for the mean-centering and scaling.

If using `part.corr = TRUE`, then you will get these two common effect size metrics on the far right two columns of the output table. However, it should be noted that these do not go hand in hand with robust standard error estimators. The standard error of the coefficient doesn't change the point estimate, just the uncertainty. However, this function uses *t*-statistics in its calculation of the partial and semipartial correlation. This provides what amounts to a heteroskedasticity-adjusted set of estimates, but I am unaware of any statistical publication that validates this type of use. Please

use these as a heuristic when used alongside robust standard errors; do not report the "robust" partial and semipartial correlations in publications.

There are two pieces of information given for `model.check`, provided that the model is an `lm` object. First, a Breusch-Pagan test is performed with `ncvTest`. This is a hypothesis test for which the alternative hypothesis is heteroskedastic errors. The test becomes much more likely to be statistically significant as the sample size increases; however, the homoskedasticity assumption becomes less important to inference as sample size increases (Lumley, Diehr, Emerson, & Lu, 2002). Take the result of the test as a cue to check graphical checks rather than a definitive decision. Note that the use of robust standard errors can account for heteroskedasticity, though some oppose this approach (see King & Roberts, 2015).

The second piece of information provided by setting `model.check` to `TRUE` is the number of high leverage observations. There are no hard and fast rules for determining high leverage either, but in this case it is based on Cook's Distance. All Cook's Distance values greater than $(4/N)$ are included in the count. Again, this is not a recommendation to locate and remove such observations, but rather to look more closely with graphical and other methods.

Value

If saved, users can access most of the items that are returned in the output (and without rounding).

<code>coefTable</code>	The outputted table of variables and coefficients
<code>model</code>	The model for which statistics are displayed. This would be most useful in cases in which <code>scale = TRUE</code> .

Much other information can be accessed as attributes.

      which.cols = NULL, ...)
```

Arguments

model	A merMod object.
scale	If TRUE, reports standardized regression coefficients. Default is FALSE.
confint	Show confidence intervals instead of standard errors? Default is FALSE.
ci.width	A number between 0 and 1 that signifies the width of the desired confidence interval. Default is .95, which corresponds to a 95% confidence interval. Ignored if confint = FALSE.
conf.method	Argument passed to <code>lme4::confint.merMod()</code> . Default is "Wald", but "profile" or "boot" are better when accuracy is a priority. Be aware that both of the alternate methods are sometimes very time-consuming.
digits	An integer specifying the number of digits past the decimal to report in the output. Default is 2. You can change the default number of digits for all jtools functions with <code>options("jtools-digits" = digits)</code> where digits is the desired number.

<code>r.squared</code>	Calculate an r-squared model fit statistic? Default is TRUE, but if it has errors or takes a long time to calculate you may want to consider setting to FALSE.
<code>pvals</code>	Show p values and significance stars? If FALSE, these are not printed. Default is TRUE, except for merMod objects (see details).
<code>n.sd</code>	If <code>scale = TRUE</code> , how many standard deviations should predictors be divided by? Default is 1, though some suggest 2.
<code>center</code>	If you want coefficients for mean-centered variables but don't want to standardize, set this to TRUE.
<code>transform.response</code>	Should scaling/centering apply to response variable? Default is FALSE.
<code>data</code>	If you provide the data used to fit the model here, that data frame is used to re-fit the model (if <code>scale</code> is TRUE) instead of the <code>stats::model.frame()</code> of the model. This is particularly useful if you have variable transformations or polynomial terms specified in the formula.
<code>exp</code>	If TRUE, reports exponentiated coefficients with confidence intervals for exponential models like logit and Poisson models. This quantity is known as an odds ratio for binary outcomes and incidence rate ratio for count models.
<code>t.df</code>	For lmerMod models only. User may set the degrees of freedom used in conducting t-tests. See details for options.
<code>model.info</code>	Toggles printing of basic information on sample size, name of DV, and number of predictors.
<code>model.fit</code>	Toggles printing of model fit statistics.
<code>re.variance</code>	Should random effects variances be expressed in standard deviations or variances? Default, to be consistent with previous versions of jtools, is "sd". Use "var" to get the variance instead.
<code>which.cols</code>	Developmental feature. By providing columns by name, you can add/remove/reorder requested columns in the output. Not fully supported, for now.
<code>...</code>	This just captures extra arguments that may only work for other types of models.

Details

By default, this function will print the following items to the console:

- The sample size
- The name of the outcome variable
- The (Pseudo-)R-squared value and AIC/BIC.
- A table with regression coefficients, standard errors, and t-values.

The `scale` and `center` options are performed via refitting the model with `scale_lm` and `center_lm`, respectively. Each of those in turn uses `gscale` for the mean-centering and scaling.

merMod models are a bit different than the others. The lme4 package developers have, for instance, made a decision not to report or compute p values for lmer models. There are good reasons for this, most notably that the t-values produced are not "accurate" in the sense of the Type I error rate. For certain large, balanced samples with many groups, this is no big deal. What's a "big" or "small" sample? How much balance is necessary? What type of random effects structure is okay? Good

luck getting a statistician to give you any clear guidelines on this. Some simulation studies have been done on fewer than 100 observations, so for sure if your sample is around 100 or fewer you should not interpret the t-values. A large number of groups is also crucial for avoiding bias using t-values. If groups are nested or crossed in a linear model, it is best to just get the **pbkrtest** package.

By default, this function follows lme4's lead and does not report the p values for lmer models. If the user has **pbkrtest** installed, however, p values are reported using the Kenward-Roger d.f. approximation unless `pvals = FALSE` or `t.df` is set to something other than `NULL`. In publications, you should cite the Kenward & Roger (1997) piece as well as either this package or **pbkrtest** package to explain how the p values were calculated.

See [pvalues](#) from the **lme4** for more details. If you're looking for a simple test with no extra packages installed, it is better to use the confidence intervals and check to see if they exclude zero than use the t-test. For users of `glmer`, see some of the advice there as well. While `lme4` and by association `summ` does as well, they are still imperfect.

You have some options to customize the output in this regard with the `t.df` argument. If `NULL`, the default, the degrees of freedom used depends on whether the user has **pbkrtest** installed. If installed, the Kenward-Roger approximation is used. If not, and user sets `pvals = TRUE`, then the residual degrees of freedom is used. If `t.df = "residual"`, then the residual d.f. is used without a message. If the user prefers to use some other method to determine the d.f., then any number provided as the argument will be used.

About pseudo-R²

There is no one way to calculate R² for mixed models or nonlinear models. Many caution against interpreting or even using such approximations outside of OLS regression. With that said, this package reports one version for your benefit, though you should of course understand that it is not an unambiguous measure of model fit.

This package calculates R² for mixed models using an adapted version of [sem.model.fits](#) from the **piecewiseSEM** package. This is an implementation of the Nakagawa & Schielzeth (2013) procedure with refinements by Johnson (2014). If you choose to report the pseudo-R² in a publication, you should cite Nakagawa & Schielzeth to explain how the calculation was done.

Value

If saved, users can access most of the items that are returned in the output (and without rounding).

<code>coeftable</code>	The outputted table of variables and coefficients
<code>rcoeftable</code>	The secondary table with the grouping variables and random coefficients.
<code>gvars</code>	The tertiary table with the grouping variables, numbers of groups, and ICCs.
<code>model</code>	The model for which statistics are displayed. This would be most useful in cases in which <code>scale = TRUE</code> .

Much other information can be accessed as attributes.

See Also

`scale_mod` can simply perform the standardization if preferred.

`gscale` does the heavy lifting for mean-centering and scaling behind the scenes.

`pbkrtest::get_ddf_Lb()` gets the Kenward-Roger degrees of freedom if you have `pbkrtest` installed.

A tweaked version of `piecewiseSEM::sem.model.fits()` is used to generate the pseudo-R-squared estimates for linear models.

Examples

```
if (requireNamespace("lme4")) {
  library(lme4, quietly = TRUE)
  data(sleepstudy)
  mv <- lmer(Reaction ~ Days + (Days | Subject), sleepstudy)

  summ(mv) # Note lack of p values if you don't have pbkrtest

  # Without pbkrtest, you'll get message about Type 1 errors
  summ(mv, pvals = TRUE)

  # To suppress message, manually specify t.df argument
  summ(mv, t.df = "residual")
}

## Not run:
# Confidence intervals may be better alternative in absence of pbkrtest
summ(mv, confint = TRUE)

## End(Not run)
```

summ.rq

*Quantile regression summaries with options***Description**

summ prints output for a regression model in a fashion similar to summary, but formatted differently with more options.

Usage

```
## S3 method for class 'rq'
summ(model, scale = FALSE, confint = getOption("summ-confint",
  FALSE), ci.width = getOption("summ-ci.width", 0.95), se = c("nid", "rank",
  "iid", "ker", "boot"), boot.sims = 1000, boot.method = "xy",
  vifs = getOption("summ-vifs", FALSE), digits = getOption("jtools-digits",
  2), pvals = getOption("summ-pvals", TRUE), n.sd = 1, center = FALSE,
  transform.response = FALSE, data = NULL,
  model.info = getOption("summ-model.info", TRUE),
  model.fit = getOption("summ-model.fit", TRUE), which.cols = NULL, ...)
```

Arguments

model	A rq model. At this time, rqs models (multiple tau parameters) are not supported.
scale	If TRUE, reports standardized regression coefficients. Default is FALSE.
confint	Show confidence intervals instead of standard errors? Default is FALSE.
ci.width	A number between 0 and 1 that signifies the width of the desired confidence interval. Default is .95, which corresponds to a 95% confidence interval. Ignored if confint = FALSE.
se	One of "nid", "rank", "iid", "ker", or "boot". "nid" is default. See quantreg::summary.rq() documentation for more about these options.
boot.sims	If se = "boot", the number of bootstrap replications to perform. This is passed as the R argument to boot.rq
boot.method	If se = "boot", the type of bootstrapping method to use. Default is "xy", but see quantreg::boot.rq() for more options.
vifs	If TRUE, adds a column to output with variance inflation factors (VIF). Default is FALSE.
digits	An integer specifying the number of digits past the decimal to report in the output. Default is 2. You can change the default number of digits for all jtools functions with options("jtools-digits" = digits) where digits is the desired number.
pvals	Show p values and significance stars? If FALSE, these are not printed. Default is TRUE.

n.sd	If <code>scale = TRUE</code> , how many standard deviations should predictors be divided by? Default is 1, though some suggest 2.
center	If you want coefficients for mean-centered variables but don't want to standardize, set this to <code>TRUE</code> .
transform.response	Should scaling/centering apply to response variable? Default is <code>FALSE</code> .
data	If you provide the data used to fit the model here, that data frame is used to re-fit the model (if <code>scale</code> is <code>TRUE</code>) instead of the <code>stats::model.frame()</code> of the model. This is particularly useful if you have variable transformations or polynomial terms specified in the formula.
model.info	Toggles printing of basic information on sample size, name of DV, and number of predictors.
model.fit	Toggles printing of model fit statistics.
which.cols	Developmental feature. By providing columns by name, you can add/remove/reorder requested columns in the output. Not fully supported, for now.
...	This just captures extra arguments that may only work for other types of models.

Details

This method implements most of the things I think most users would asking `summary.rq` for. `hs`, `U`, and `gamma` are ignored.

Note that when using `se = "rank"`, there are no standard errors, test statistics, or p values calculated.

About the `R1` fit statistic: Described in Koenker & Machado (1999), this offers an interpretation similar to R-squared in OLS regression. While you could calculate R-squared for these models, it goes against the underlying theoretical rationale for them. Koenker himself is not a big fan of `R1` either, but it's something. See Koenker & Machado (1999) for more info.

Examples

```
if (requireNamespace("quantreg")) {
  library(quantreg)
  data(engel)
  fitrq <- rq(income ~ foodexp, data = engel, tau = 0.5)
  summ(fitrq)
}
```

 summ.svyglm

Complex survey regression summaries with options

Description

summ prints output for a regression model in a fashion similar to summary, but formatted differently with more options.

Usage

```
## S3 method for class 'svyglm'
summ(model, scale = FALSE,
      confint = getOption("summ-confint", FALSE),
      ci.width = getOption("summ-ci.width", 0.95),
      digits = getOption("jtools-digits", default = 2),
      pvals = getOption("summ-pvals", TRUE), n.sd = 1, center = FALSE,
      transform.response = FALSE, exp = FALSE, vifs = getOption("summ-vifs",
      FALSE), model.info = getOption("summ-model.info", TRUE),
      model.fit = getOption("summ-model.fit", TRUE), model.check = FALSE,
      which.cols = NULL, ...)
```

Arguments

model	A svyglm object.
scale	If TRUE, reports standardized regression coefficients. Default is FALSE.
confint	Show confidence intervals instead of standard errors? Default is FALSE.
ci.width	A number between 0 and 1 that signifies the width of the desired confidence interval. Default is .95, which corresponds to a 95% confidence interval. Ignored if confint = FALSE.
digits	An integer specifying the number of digits past the decimal to report in the output. Default is 2. You can change the default number of digits for all jtools functions with options("jtools-digits" = digits) where digits is the desired number.
pvals	Show p values and significance stars? If FALSE, these are not printed. Default is TRUE.
n.sd	If scale = TRUE, how many standard deviations should predictors be divided by? Default is 1, though some suggest 2.
center	If you want coefficients for mean-centered variables but don't want to standardize, set this to TRUE.
transform.response	Should scaling/centering apply to response variable? Default is FALSE.
exp	If TRUE, reports exponentiated coefficients with confidence intervals for exponential models like logit and Poisson models. This quantity is known as an odds ratio for binary outcomes and incidence rate ratio for count models.

vifs	If TRUE, adds a column to output with variance inflation factors (VIF). Default is FALSE.
model.info	Toggles printing of basic information on sample size, name of DV, and number of predictors.
model.fit	Toggles printing of model fit statistics.
model.check	Toggles whether to perform Breusch-Pagan test for heteroskedasticity and print number of high-leverage observations. See details for more info.
which.cols	Developmental feature. By providing columns by name, you can add/remove/reorder requested columns in the output. Not fully supported, for now.
...	This just captures extra arguments that may only work for other types of models.

Details

By default, this function will print the following items to the console:

- The sample size
- The name of the outcome variable
- The (Pseudo-)R-squared value and AIC.
- A table with regression coefficients, standard errors, t values, and p values.

The scale and center options are performed via refitting the model with [scale_lm](#) and [center_lm](#), respectively. Each of those in turn uses [gscale](#) for the mean-centering and scaling. These functions can handle `svyglm` objects correctly by calling `svymean` and `svyvar` to compute means and standard deviations. Weights are not altered. The fact that the model is refit means the runtime will be similar to the original time it took to fit the model.

Value

If saved, users can access most of the items that are returned in the output (and without rounding).

coeftable	The outputted table of variables and coefficients
model	The model for which statistics are displayed. This would be most useful in cases in which <code>scale = TRUE</code> .

Much other information can be accessed as attributes.

[scale_lm](#) can simply perform the standardization if preferred.

[gscale](#) does the heavy lifting for mean-centering and scaling behind the scenes.

Examples

```

if (requireNamespace("survey")) {
  library(survey)
  data(api)
  dstrat <- svydesign(id = ~1, strata =~ stype, weights =~ pw,
                    data = apistrat, fpc =~ fpc)
  regmodel <- svyglm(api00 ~ ell * meals, design = dstrat)

  summ(regmodel)
}

```

svycor

*Calculate Pearson correlations with complex survey data***Description**

svycor extends the survey package by calculating correlations with syntax similar to the original package, which for reasons unknown lacks such a function.

Usage

```
svycor(formula, design, na.rm = FALSE, digits = getOption("jtools-digits",
  default = 2), sig.stats = FALSE, bootn = 1000, mean1 = TRUE, ...)
```

Arguments

formula	A formula (e.g., ~var1+var2) specifying the terms to correlate.
design	The survey.design or svyrep.design object.
na.rm	Logical. Should cases with missing values be dropped?
digits	An integer specifying the number of digits past the decimal to report in the output. Default is 2. You can change the default number of digits for all jtools functions with options("jtools-digits" = digits) where digits is the desired number.
sig.stats	Logical. Perform non-parametric bootstrapping (using wtd.cor) to generate standard errors and associated t- and p-values. See details for some considerations when doing null hypothesis testing with complex survey correlations.
bootn	If sig.stats is TRUE, this defines the number of bootstraps to be run to generate the standard errors and p-values. For large values and large datasets, this can contribute considerably to processing time.
mean1	If sig.stats is TRUE, it is important to know whether the sampling weights should have a mean of 1. That is, should the standard errors be calculated as if the number of rows in your dataset is the total number of observations (TRUE) or as if the sum of the weights in your dataset is the total number of observations (FALSE)?
...	Additional arguments passed to svyvar .

Details

This function extends the survey package by calculating the correlations for user-specified variables in survey design and returning a correlation matrix.

Using the [wtd.cor](#) function, this function also returns standard errors and p-values for the correlation terms using a sample-weighted bootstrapping procedure. While correlations do not require distributional assumptions, hypothesis testing (i.e., $r > 0$) does. The appropriate way to calculate standard errors and use them to define a probability is not straightforward in this scenario since the weighting causes heteroskedasticity, thereby violating an assumption inherent in the commonly used methods for converting Pearson's correlations into t-values. The method provided here is defensible, but if reporting in scientific publications the method should be spelled out.

Value

If significance tests are not requested, there is one returned value:

`cors` The correlation matrix (without rounding)

If significance tests are requested, the following are also returned:

`p.values` A matrix of p values

`t.values` A matrix of t values

`std.err` A matrix of standard errors

Note

This function was designed in part on the procedure recommended by Thomas Lumley, the author of the survey package, on [Stack Overflow](#). However, he has not reviewed or endorsed this implementation. All defects are attributed to the author.

Author(s)

Jacob Long <<long.1377@osu.edu>>

See Also

[wtd.cor](#), [svyvar](#)

Other **survey** package extensions: [svysd](#)

Other survey tools: [pf_sv_test](#), [svysd](#), [weights_tests](#), [wgttest](#)

Examples

```
if (requireNamespace("survey")) {
  library(survey)
  data(api)
  # Create survey design object
  dstrat <- svydesign(id = ~1, strata = ~stype, weights = ~pw,
                   data = apistrat, fpc = ~fpc)

  # Print correlation matrix
```

```
svycor(~api00 + api99 + dnum, design = dstrat)

# Save the results, extract correlation matrix
out <- svycor(~api00 + api99 + dnum, design = dstrat)
out$cors

}
```

svysd

Calculate standard deviations with complex survey data

Description

svysd extends the survey package by calculating standard deviations with syntax similar to the original package, which provides only a [svyvar](#) function.

Usage

```
svysd(formula, design, na.rm = FALSE, digits = getOption("jtools-digits",
  default = 3), ...)
```

Arguments

formula	A formula (e.g., ~var1+var2) specifying the term(s) of interest.
design	The survey.design or svyrep.design object.
na.rm	Logical. Should cases with missing values be dropped?
digits	An integer specifying the number of digits past the decimal to report in the output. Default is 3. You can change the default number of digits for all jtools functions with <code>options("jtools-digits" = digits)</code> where digits is the desired number.
...	Additional arguments passed to svyvar .

Details

An alternative is to simply do `sqrt(svyvar(~term, design = design))`. However, if printing and sharing the output, this may be misleading since the output will say "variance."

Note

This function was designed independent of the **survey** package and is neither endorsed nor known to its authors.

  data(api)
  # Create survey design object
  dstrat <- svydesign(id = ~1, strata = ~stype, weights = ~pw, data = apistrat,
                   fpc=~fpc)

  # Print the standard deviation of some variables
  svysd(~api00+ell+meals, design = dstrat)
}
```

 theme_apa

Format ggplot2 figures in APA style

Description

theme_apa() is designed to work like any other complete theme from [ggplot](#). To the extent possible, it aligns with the (vague) APA figure guidelines.

Usage

```
theme_apa(legend.pos = "right", legend.use.title = FALSE,
          legend.font.size = 12, x.font.size = 12, y.font.size = 12,
          facet.title.size = 12, remove.y.gridlines = TRUE,
          remove.x.gridlines = TRUE)
```

Arguments

legend.pos	One of "right", "left", "top", "bottom", "topleft", "topright", "topmiddle", "bottomleft", "bottomright", or "bottommiddle". Positions the legend, which will layer on top of any geoms, on the plane.
legend.use.title	Logical. Specify whether to include a legend title. Defaults to FALSE.
legend.font.size	Integer indicating the font size of the labels in the legend. Default and APA-recommended is 12, but if there are many labels it may be necessary to choose a smaller size.
x.font.size	Font size of x-axis label.
y.font.size	Font size of x-axis label.
facet.title.size	Font size of facet labels.
remove.y.gridlines	Should the coordinate grid on the y-axis (horizontal lines) be removed? Default is TRUE.
remove.x.gridlines	Should the coordinate grid on the x-axis (vertical lines) be removed? Default is TRUE.

Details

This function applies a theme to `ggplot2` figures with a style that is roughly in line with APA guidelines. Users may need to perform further operations for their specific use cases.

There are some things to keep in mind about APA style figures:

- Main titles should be written in the word processor or typesetter rather than on the plot image itself.
- In some cases, users can forgo a legend in favor of describing the figure in a caption (also written in the word processor/typesetter).
- Legends are typically embedded on the coordinate plane of the figure rather than next to it, as is default in `ggplot2`.
- Use of color is generally discouraged since most of the applications for which APA figures are needed involve eventual publication in non-color print media.
- There are no hard and fast rules on font size, though APA recommends choosing between 8 and 14-point. Fonts in figures should be sans serif.

Because APA style calls for positioning legends on the plane itself, this function includes options for choosing a position—top left, top right, bottom left, bottom right—to place the legend. `ggplot2` provides no obvious way to automatically choose a position that overlaps least with the geoms (the plotted data), so users will need to choose one.

Facetting is supported, but APA guidelines are considerably less clear for such situations.

This theme was created with inspiration from Rudolf Cardinal's [code](#), which required updating for newer versions of `ggplot2` and adaptations for APA style.

tidy.summ

Broom extensions for summ objects

Description

These are functions used for compatibility with broom's tidying functions to facilitate use with huxreg, thereby making [export_summs](#) works.

Usage

```
tidy.summ(x, conf.int = FALSE, conf.level = 0.95, ...)

glance.summ.lm(x, ...)

glance.summ.glm(x, ...)

glance.summ.svyglm(x, ...)

glance.summ.merMod(x, ...)

tidy.sim_slopes(x, conf.int = FALSE, conf.level = 0.95, ...)

glance.summ.rq(x, ...)
```

Arguments

x	The summ object.
conf.int	Include confidence intervals? Default is FALSE.
conf.level	How wide confidence intervals should be, if requested. Default is .95.
...	Other arguments (usually ignored)

Value

A data.frame with columns matching those appropriate for the model type per glance documentation.

See Also

[glance](#)

weights_tests	<i>Test whether sampling weights are needed</i>
---------------	---

Description

Use the tests proposed in Pfeiffermann and Sverchkov (1999) and DuMouchel and Duncan (1983) to check whether a regression model is specified correctly without weights.

Usage

```
weights_tests(model, weights, data, model_output = TRUE, test = NULL,
             sims = 1000, digits = getOption("jtools-digits", default = 2))
```

Arguments

model	The fitted model, without weights
weights	The name of the weights column in model's data frame or a vector of weights equal in length to the number of observations included in model.
data	The data frame with the data fed to the fitted model and the weights
model_output	Should a summary of the model with weights as predictor be printed? Default is TRUE, but you may not want it if you are trying to declutter a document.
test	Which type of test should be used in the ANOVA? The default, NULL, chooses based on the model type ("F" for linear models). This argument is passed to anova.
sims	The number of bootstrap simulations to use in estimating the variance of the residual correlation. Default is 1000, but for publications or when computing power/time is sufficient, a higher number is better.
digits	An integer specifying the number of digits past the decimal to report in the output. Default is 3. You can change the default number of digits for all jtools functions with <code>options("jtools-digits" = digits)</code> where digits is the desired number.

Details

This function is a wrapper for the two tests implemented in this package that test whether your regression model is correctly specified. The first is `wgttest`, an R adaptation of the Stata macro of the same name. This test can otherwise be referred to as the DuMouchel-Duncan test. The other test is the Pfeiffermann-Sverchkov test, which can be accessed directly with `pf_sv_test`.

For more details on each, visit the documentation on the respective functions. This function just runs each of them for you.

Other survey tools: [pf_sv_test](#), [svycor](#), [svysd](#), [wgttest](#)

Examples

```
# Note: This is a contrived example to show how the function works,
# not a case with actual sampling weights from a survey vendor
if (requireNamespace("boot")) {
  states <- as.data.frame(state.x77)
  set.seed(100)
  states$wts <- runif(50, 0, 3)
  fit <- lm(Murder ~ Illiteracy + Frost, data = states)
  weights_tests(model = fit, data = states, weights = wts, sims = 100)
}
```

wgttest

Test whether sampling weights are needed

Description

Use the DuMouchel-Duncan (1983) test to assess the need for sampling weights in your linear regression analysis.

Usage

```
wgttest(model, weights, data = NULL, model_output = FALSE, test = NULL,
  digits = getOption("jtools-digits", default = 3))
```

Arguments

- | | |
|---------|--|
| model | The unweighted linear model (must be <code>lm</code> , <code>glm</code> , see details for other types) you want to check. |
| weights | The name of the weights column in model's data frame or a vector of weights equal in length to the number of observations included in model. |
| data | The data frame with the data fed to the fitted model and the weights |

<code>model_output</code>	Should a summary of the model with weights as predictor be printed? Default is FALSE since the output can be very long for complex models.
<code>test</code>	Which type of test should be used in the ANOVA? The default, NULL, chooses based on the model type ("F" for linear models). This argument is passed to <code>anova</code> .
<code>digits</code>	An integer specifying the number of digits past the decimal to report in the output. Default is 3. You can change the default number of digits for all <code>jtools</code> functions with <code>options("jtools-digits" = digits)</code> where <code>digits</code> is the desired number.

Details

This is designed to be similar to the `wgttest` macro for Stata (<http://fmwww.bc.edu/repec/bocode/w/wgttest.html>). This method, advocated for by DuMouchel and Duncan (1983), is fairly straightforward. To decide whether weights are needed, the weights are added to the linear model as a predictor and interaction with each other predictor. Then, an omnibus test of significance is performed to compare the weights-added model to the original; if insignificant, weights are not significantly related to the result and you can use the more efficient estimation from unweighted OLS.

It can be helpful to look at the created model using `model_output = TRUE` to see which variables might be the ones affected by inclusion of weights.

This test can support most GLMs in addition to LMs, a use validated by Nordberg (1989). This, to my knowledge, is different from the Stata macro. It does not work for mixed models (e.g., `lmer` or `lme`) though it could plausibly be implemented. However, there is no scholarly consensus how to properly incorporate weights into mixed models. There are other types of models that may work, but have not been tested. The function is designed to be compatible with as many model types as possible, but the user should be careful to make sure s/he understands whether this type of test is appropriate for the model being considered. DuMouchel and Duncan (1983) were only thinking about linear regression when the test was conceived. Nordberg (1989) validated its use with generalized linear models, but to this author's knowledge it has not been tested with other model types.

Examples

```
# First, let's create some fake sampling weights
wts <- runif(50, 0, 5)
# Create model
fit <- lm(Income ~ Frost + Illiteracy + Murder,
          data = as.data.frame(state.x77))
# See if the weights change the model
wgttest(fit, weights = wts)

# With a GLM
wts <- runif(100, 0, 2)
x <- rnorm(100)
y <- rbinom(100, 1, .5)
fit <- glm(y ~ x, family = binomial)
wgttest(fit, wts)
## Can specify test manually
wgttest(fit, weights = wts, test = "Rao")

# Quasi family is treated differently than likelihood-based
## Dobson (1990) Page 93: Randomized Controlled Trial (plus some extra values):
counts <- c(18,17,15,20,10,20,25,13,12,18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,18)
treatment <- gl(3,6)
glm.D93 <- glm(counts ~ outcome + treatment, family = quasipoisson)
wts <- runif(18, 0, 3)
wgttest(glm.D93, weights = wts)
```
