Package 'ddalpha'

January 6, 2019

Type Package

Title Depth-Based Classification and Calculation of Data Depth

Version 1.3.8

Date 2019-01-06

SystemRequirements C++11

Depends R (>= 2.10), stats, utils, graphics, grDevices, MASS, class, robustbase, sfsmisc, geometry

Imports Rcpp (>= 0.11.0)

LinkingTo BH, Rcpp

Description Contains procedures for depth-based supervised learning, which are entirely non-parametric, in particular the DDalpha-procedure (Lange, Mosler and Mozharovskyi, 2014 <doi:10.1007/s00362-012-0488-4>). The training data sample is transformed by a statistical depth function to a compact low-dimensional space, where the final classification is done. It also offers an extension to functional data and routines for calculating certain notions of statistical depth functions. 50 multivariate and 5 functional classification problems are included.

`ddalpha-package` *Depth-Based Classification and Calculation of Data Depth*

Description

The package provides many procedures for calculating the depth of points in an empirical distribution for many notions of data depth. Further it provides implementations for depth-based classification, for multivariate and functional data.

The package implements the DDα-classifier (Lange, Mosler and Mozharovskyi, 2014), a nonparametric procedure for supervised binary classification with $q \geq 2$ classes. In the training step, the sample is first transformed into a q-dimensional cube of depth vectors, then a linear separation rule in its polynomial extension is constructed with the α-procedure. The classification step involves alternative treatments of 'outsiders'.

Details

Package:	ddalpha
Type:	Package
Version:	1.3.8
Date:	2019-01-06
License:	GPL-2

Use `ddalpha.train` to train the DD-classifier and `ddalpha.classify` to classify with it. Load sample classification problems using `getdata`. The package contains 50 classification problems built of 33 sets of real data.

The list of the implemented multivariate depths is found in topic `depth.`, for functional depths see `depthf.`. The depth representations of the multivariate data are obtained with `depth.space.`. Functions `depth.contours` and `depth.contours.ddalpha` build depth contours, and `depth.graph` builds depth graphs for two-dimensional data. Function `draw.ddplot` draws DD-plot for the existing DD-classifier, or for pre-calculated depth space.

The package supports user-defined depths and classifiers, see topic `Custom Methods`. A pre-calculated DD-plot may also be used as `data`, see topic `ddalpha.train`.

`is.in.convex` shows whether an object is no 'outsider', i.e. can be classified by its depth values. Outsiders are alternatively classified by LDA, kNN and maximum Mahalanobis depth as well as by random assignment.

Use `compclassf.train` and `ddalphaf.train` to train the functional DD-classifiers and `compclassf.classify` `ddalpha.classify` to classify with them. Load sample functional classification problems with `dataf.*`. The package contains 4 functional data sets and 2 data set generators. The functional data are visualized with `plot.functional`.

```

`Cmetric` *Fast Computation of the Uniform Metric for Sets of Functional Data*

Description

Returns the matrix of C (uniform) distances between two sets of functional data.

Usage

```
Cmetric(A, B)
```

Arguments

`A`	Functions of the first set, represented by a matrix of their functional values of size `m*d`. `m` stands for the number of functions, `d` is the number of the equidistant points in the domain of the data at which the functional values of the `m` functions are evaluated.
`B`	Functions of the second set, represented by a matrix of their functional values of size `n*d`. `n` stands for the number of functions, `d` is the number of the equidistant points in the domain of the data at which the functional values of the `n` functions are evaluated. The grid of observation points for the functions `A` and `B` must be the same.

Details

For two sets of functional data of sizes `m` and `n` represented by matrices of their functional values, this function returns the symmetric matrix of size `m*n` whose entry in the `i`-th row and `j`-th column is the approximated C (uniform) distance of the `i`-th function from the first set, and the `j`-th function from the second set. This function is utilized in the computation of the h-mode depth.

Value

A symmetric matrix of the distances of the functions of size `m*n`.

compclassf.classify *Classify using Functional Componentwise Classifier*

Description

Classifies data using the functional componentwise classifier.

Usage

```
compclassf.classify(compclassf, objectsf, subset, ...)

## S3 method for class 'compclassf'
predict(object, objectsf, subset, ...)
```

Arguments

compclassf, object	Functional componentwise classifier (obtained by compclassf.train).
objectsf	list containing lists (functions) of two vectors of equal length, named "args" and "vals": arguments sorted in ascending order and corresponding them values respectively
subset	an optional vector specifying a subset of observations to be classified.
...	additional parameters, passed to the classifier, selected with parameter classifier.type in compclassf.train.

Value

List containing class labels.

References

See Also

`compclassf.train` to train the functional componentwise classifier.

Examples

```
## Not run:
## load the Growth dataset
dataf = dataf.growth()

learn = c(head(dataf$dataf, 49), tail(dataf$dataf, 34))
labels =c(head(dataf$labels, 49), tail(dataf$labels, 34))
test = tail(head(dataf$dataf, 59), 10)    # elements 50:59. 5 girls, 5 boys

c = compclassf.train (learn, labels, classifier.type = "ddalpha")

classified = compclassf.classify(c, test)

print(unlist(classified))

## End(Not run)
```

`compclassf.train` *Functional Componentwise Classifier*

Description

Trains the functional componentwise classifier

Usage

```
compclassf.train (dataf, labels, subset,
                  to.equalize = TRUE,
                  to.reduce = TRUE,
                classifier.type = c("ddalpha", "maxdepth", "knnaff", "lda", "qda"),
                  ...)
```

Arguments

`dataf`	list containing lists (functions) of two vectors of equal length, named "args" and "vals": arguments sorted in ascending order and corresponding them values respectively

`labels`	list of output labels of the functional observations
`subset`	an optional vector specifying a subset of observations to be used in training the classifier.
`to.equalize`	Adjust the data to have equal (the largest) argument interval.
`to.reduce`	If the data spans a subspace only, project on it (by PCA).
`classifier.type`	the classifier which is used on the transformed space. The default value is 'ddalpha'.
`...`	additional parameters, passed to the classifier, selected with parameter `classifier.type`.

Details

The finite-dimensional space is directly constructed from the observed values. Delaigle, Hall and Bathia (2012) consider (almost) all sets of discretization points that have a given cardinality.

The usual classifiers are then trained on the constructed finite-dimensional space.

Value

Trained functional componentwise classifier

References

dataf = dataf.growth()

learn = c(head(dataf$dataf, 49), tail(dataf$dataf, 34))
labels =c(head(dataf$labels, 49), tail(dataf$labels, 34))
test = tail(head(dataf$dataf, 59), 10)    # elements 50:59. 5 girls, 5 boys

c = compclassf.train (learn, labels, classifier.type = "ddalpha")

classified = compclassf.classify(c, test)

print(unlist(classified))
```

```
## End(Not run)
```

`Custom Methods` *Using Custom Depth Functions and Classifiers*

Description

To use a custom depth function or classifier one has to implement three functions: parameters validator, learning and calculating functions.

Details

To define a depth function:

.<NAME>_validate validates parameters passed to `ddalpha.train` and passes them to the `ddalpha` object.

IN:

`ddalpha`	the ddalpha object, containing the data and settings (mandatory)
`<custom parameters>`	parameters that are passed to the user-defined method
`...`	other parameters (mandatory)

OUT:

`list()`	list of output parameters, after the validation is finished, these parameters are stored in the `ddalpha`

.<NAME>_learn trains the depth

IN:

`ddalpha`	the ddalpha object, containing the data and settings

MODIFIES:

`ddalpha`	store the calculated statistics in the `ddalpha` object
depths	calculate the depths of each pattern, e.g. `for (i in 1:ddalpha$numPatterns) ddalpha$patterns[[i]]$depths = .<NAME>_depths(ddalpha, c`

OUT:

`ddalpha`	the updated `ddalpha` object

.<NAME>_depths calculates the depths

IN:

`ddalpha`	the ddalpha object, containing the data and settings
`objects`	the objects for which the depths are calculated

OUT:

`depths`	the calculated depths for each object (rows), with respect to each class (cols)

Usage: `ddalpha.train(data, depth = "<NAME>", <custom parameters>, ...)`
Custom depths

```
.MyDepth_validate  <- function(ddalpha, mydepth.parameter = "value", ...){
 print("MyDepth validating")
 # validate the parameters
 if (!is.valid(mydepth.parameter)){
  warning("Argument \"mydepth.parameter\" not specified correctly. Default value is used")
  mydepth.parameter = "value"
  # or stop("Argument \"mydepth.parameter\" not specified correctly.")
 }
 # the values from the return list will be stored in the ddalpha object
 return (list(mydepthpar = mydepth.parameter))
}
.MyDepth_learn <- function(ddalpha){
 print("MyDepth learning")
 #1. Calculate any statistics based on data that .MyDepth_depths needs
 #   and store them to the ddalpha object:
 ddalpha$mydepth.statistic = "some value"
 #2. Calculate depths for each pattern
 for (i in 1:ddalpha$numPatterns){
  ddalpha$patterns[[i]]$depths = .MyDepth_depths(ddalpha, ddalpha$patterns[[i]]$points)
 }
 return(ddalpha)
}
.MyDepth_depths <- function(ddalpha, objects){
 print("MyDepth calculating")
 depths <- NULL
 # The depth parameters are accessible in the ddalpha object:
 mydepth.parameter = ddalpha$mydepth.parameter
 mydepth.statistic = ddalpha$mydepth.statistic
 #calculate the depths of the objects w.r.t. each pattern
 for (i in 1:ddalpha$numPatterns){
  depth_wrt_i = #calculate depths of the objects, as vector
  depths <- cbind(depths, depth_wrt_i)
 }
 return (depths)
}
ddalpha.train(data, depth = "MyDepth", ...)
```

To define a classifier:

.<NAME>_validate validates parameters passed to `ddalpha.train` and passes them to the `ddalpha` object

IN:

`ddalpha`	the ddalpha object, containing the data and settings (mandatory)
`<custom parameters>`	parameters that are passed to the user-defined method
`...`	other parameters (mandatory)

OUT:

`list()`	list of output parameters, after the validation is finished, these parameters are stored in the `ddalpha`

.<NAME>_learn trains the classifier. Is different for binnary and mylticlass classifiers.

IN:

`ddalpha`	the ddalpha object, containing the data and settings
`index1`	(only for binary) index of the first class
`index2`	(only for binary) index of the second class
`depths1`	(only for binary) depths of the first class w.r.t. all classes
`depths2`	(only for binary) depths of the second class w.r.t. all classes
	depths w.r.t. only given classes are received by `depths1[,c(index1, index2)]`
	for the multiclass classifiers the depths are accessible via `ddalpha$patterns[[i]]$depths`

OUT:

`classifier`	the trained `classifier` object

.<NAME>_classify classifies the objects

IN:

`ddalpha`	the ddalpha object, containing the data and global settings
`classifier`	the previously trained classifier
`objects`	the objects (depths) that are classified

OUT:

`result`	a vector with classification results (binary) the objects from class `"classifier$index1"` get positive values (multiclass) the objects get the numbers of patterns in `ddalpha`

Usage: `ddalpha.train(data, separator = "<NAME>", ...)`

```
#### Custom classifiers ####
.MyClassifier_validate  <- function(ddalpha, my.parameter = "value", ...){
 print("MyClassifier validating")
 # validate the parameters
 ...
 # always include methodSeparatorBinary.
 # TRUE for the binary classifier, FALSE otherwise
 return(list(methodSeparatorBinary = T,
         my.parameter = my.parameter
         ))
}
# a binary classifier
# the package takes care of the voting procedures. Just train it as if there are only two classes
.MyClassifier_learn <- function(ddalpha, index1, index2, depths1, depths2){
 print("MyClassifier (binary) learning")
 # The parameters are accessible in the ddalpha object:
 my.parameter = ddalpha$my.parameter
 #depths w.r.t. only given classes are received by
 depths1[,c(index1, index2)]
 depths2[,c(index1, index2)]
 # train the classifier
 classifier <-  ...
```

```
  #return the needed values in a list, e.g.
  return(list(
    coefficients  = classifier$coefficients,
    ... ))
}
# a multiclass classifier
.MyClassifier_learn <- function(ddalpha){
  print("MyClassifier (multiclass) learning")
  # access the data through the ddalpha object, e.g.
  for (i in 1:ddalpha$numPatterns){
    depth  <- ddalpha$patterns[[i]]$depths
    number <- ddalpha$patterns[[i]]$cardinality
    ...
  }
  # train the classifier
  classifier <-  ...
  # return the classifier
  return(classifier)
}
# the interface of the classify function is equal for binary and multiclass classifiers
.MyClassifier_classify <- function(ddalpha, classifier, depths){
  print("MyClassifier classifying")
  # The global parameters are accessible in the ddalpha object:
  my.parameter = ddalpha$my.parameter
  # The parameters generated by .MyClassifier_learn are accessible in the classifier object:
  classifier$coefficients
  # here are the depths w.r.t. the first class
  depths[,classifier$index1]
  # here are the depths w.r.t. the second class
  depths[,classifier$index2]
  # fill results in a vector, so that:
  # (binary) the objects from class "classifier$index1" get positive values
  # (multiclass) the objects get the numbers of patterns in ddalpha
  result <- ...
  return(result)
}
ddalpha.train(data, separator = "MyClassifier", ...)
```

dataf.* *Functional Data Sets*

Description

The functions generate data sets of functional two-dimensional data of two or more classes.

Usage

```
# dataf.[name]()
```

```
# load the data set by name
# data(list = "name")

# load the data set by name to a variable
# getdata("name")
```

Format

The functional data as a data structure.

`dataf` The functional data as a list of objects. Each object is characterized by two coordinates

- `args` The arguments vector
- `vals` The values vector

`labels` The classes of the objects

Details

More details about the datasets in the topics:

dataf.geneexp *Gene Expression Profile Data*

Description

A subet of the Drosophila life cycle gene expression data of Arbeitman et al. (2002). The original data set contains 77 gene expression profiles during 58 sequential time points from the embryonic, larval, and pupal periods of the life cycle. The gene expression levels were obtained by a cDNA microarray experiment.

Usage

```
dataf.geneexp()
```

Format

The functional data as a data structure.

`dataf` The functional data as a list of objects. Each object is characterized by two coordinates.

- `args` **Time** - a numeric vector of time periods
- `vals` **Gene Expression Level** - a numeric vector

`labels` Biological classifications identified in Arbeitman et al.(2002) (1 = transient early zygotic genes; 2 = muscle-specific genes; 3 = eye-specific genes.)

  colors = c("red", "green", "blue"))

## End(Not run)
```

`dataf.growth` *Berkeley Growth Study Data*

Description

The data set contains the heights of 39 boys and 54 girls from age 1 to 18 and the ages at which they were collected.

Usage

```
dataf.growth()
```

Format

The functional data as a data structure.

`dataf` The functional data as a list of objects. Each object is characterized by two coordinates

- `args` **age** - a numeric vector of length 31 giving the ages at which the heights were measured
- `vals` **height** - a numeric vector of heights in centimeters of 39 boys and 54 girls

`labels` The classes of the objects: boy, girl

Details

The ages are not equally spaced.

dataf.medflies *Relationship of Age Patterns of Fecundity to Mortality for Female Medflies.*

Description

The data set consists of number of eggs laid daily for each of 1000 medflies (Mediterranean fruit flies, Ceratitis capitata) until time of death. Data were obtained in Dr. Carey's laboratory. The main questions are to explore the relationship of age patterns of fecundity to mortality, longevity and lifetime reproduction.

A basic finding was that individual mortality is associated with the time-dynamics of the egg-laying trajectory. An approximate parametric model of the egg laying process was developed and used in Muller et al. (2001). Non-parametric approaches which extend principal component analysis for curve data to the situation when covariates are present have been developed and discussed in Chiou, Muller and Wang (2003) and Chiou et al. (2003).

Usage

```
dataf.medflies()
```

Format

The functional data as a data structure.

`dataf` The functional data as a list of objects. Each object is characterized by two coordinates.

- `args` **day** - a numeric vector of the days numbers
- `vals` **#eggs** - a numeric vector of numbers of eggs laid daily

`labels` The classes of the objects: long-lived, short-lived

`dataf.population` *World Historical Population-by-Country Dataset*

Description

Historical world population data by countries.

Usage

```
dataf.population()
```

Format

The functional data as a data structure.

`dataf` The functional data as a list of objects. Each object is characterized by two coordinates

- `args` **year** - a numeric vector of years 1950-2015 (66 years)
- `vals` **population** - a numeric vector of the estimated total population in thousands in 233 countries and regions

`labels` The geographic region of the country: Africa, Asia, Europe, Latin America, North America, Oceania

`identifier` The name of country or region

Details

World population data by a country, area or region as of 1 July of the year indicated. Figures are presented in thousands.

`dataf.sim.1.CFF07` *Model 1 from Cuevas et al. (2007)*

Description

Model 1 from Cuevas et al. (2007)

Processes:
X(t) = m_0(t) + e(t), m_0(t) = 30*(1-t)*t^1.2
Y(t) = m_1(t) + e(t), m_1(t) = 30*(1-t)^1.2*t
e(t): Gaussian with mean = 0, cov(X(s), X(t)) = 0.2*exp(-abs(s - t)/0.3)
the processes are discretized at `numDiscrets` equally distant points on [0, 1]. The functions are smooth and differ in mean only, which makes the classification task rather simple.

Usage

```
dataf.sim.1.CFF07(numTrain = 100, numTest = 50, numDiscrets = 51, plot = FALSE)
```

Arguments

`numTrain`	number of objects in the training sample
`numTest`	number of objects in the test sample
`numDiscrets`	number of points for each object
`plot`	if TRUE the training sample is plotted

Format

A data strusture containing `$learn` and `$test` functional data. The functional data are given as data structures.

`dataf` The functional data as a list of objects. Each object is characterized by two coordinates.

- `args` a numeric vector
- `vals` a numeric vector

`labels` The classes of the objects: 0 for X(t), 1 for Y(t)

Source

Cuevas, A., Febrero, M. and Fraiman, R. (2007). Robust estimation and classification for functional data via projection-based depth notions. Computational Statistics 22 481-496.

dataf = dataf.sim.1.CFF07(numTrain = 100, numTest = 50, numDiscrets = 51, plot = TRUE)

## End(Not run)
```

`dataf.sim.2.CFF07` *Model 2 from Cuevas et al. (2007)*

Description

Model 2 from Cuevas et al. (2007)

Processes:
X(t) = m_0(t) + e(t), m_0(t) = 30*(1-t)*t^2 + 0.5*abs(sin(20*pi*t))
Y(t) = an 8-knot spline approximation of X
e(t): Gaussian with mean = 0, cov(X(s), X(t)) = 0.2*exp(-abs(s - t)/0.3)
the processes are discretized at `numDiscrets` equally distant points on [0, 1].

Usage

```
dataf.sim.2.CFF07(numTrain = 100, numTest = 50, numDiscrets = 51, plot = FALSE)
```

Arguments

`numTrain`	number of objects in the training sample
`numTest`	number of objects in the test sample
`numDiscrets`	number of points for each object
`plot`	if TRUE the training sample is plotted

Format

A data strusture containing `$learn` and `$test` functional data. The functional data are given as data structures.

`dataf` The functional data as a list of objects. Each object is characterized by two coordinates.

## End(Not run)
```

---

dataf.tecator *Functional Data Set Spectrometric Data (Tecator)*

Description

This dataset is a part of the original one which can be found at http://stat.cmu.edu. For each peace of finely chopped meat we observe one spectrometric curve which corresponds to the absorbance measured at 100 wavelengths. The peaces are split according to Ferraty and Vieu (2006) into two classes: with small (<20) and large fat content obtained by an analytical chemical processing.

Usage

```
dataf.tecator()
```

Format

The functional data as a data structure.

`dataf` The functional data as a list of objects. Each object is characterized by two coordinates.

- `args` **wavelength** - a numeric vector of discretization points from 850 to 1050mm
- `vals` **absorbance** - a numeric vector of absorbance values

`labels` The classes of the objects: "small" (<20) and "large" fat content

Author(s)

Febrero-Bande, M and Oviedo de la Fuente, Manuel

Source

http://stat.cmu.edu

    colors = c("blue", "red"))

## End(Not run)
```

dataf2rawfd *Transform a* dataf *Object to Raw Functional Data*

Description

From a (possibly multivariate) functional data object dataf constructs an array of the functional values evaluated at an equi-distant grid of points.

Usage

```
dataf2rawfd(dataf, range = NULL, d = 101)
```

Arguments

dataf	Functions to be transformed, represented by a (possibly multivariate) dataf object of their arguments and functional values. m stands for the number of functions. The grid of observation points for the functions in dataf may not be the same.
range	The common range of the domain where the functions dataf are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in dataf. If the range is not provided, the smallest interval in which all the arguments from the data functions are contained is chosen as the domain.
d	Grid size to which all the functional data are transformed. All functional observations are transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation, see Nagy et al. (2016).

Value

If the functional data are univariate (scalar-valued), a matrix of size m*d is given, with each row corresponding to one function. If the functional data are k-variate with k>1, an array of size m*d*k of the functional values is given.

Author(s)

Stanislav Nagy, <nagy at karlin.mff.cuni.cz>

dataf2rawfd(R,range=c(-1,1),d=50)
```

---

ddalpha.classify *Classify using DD-Classifier*

Description

Classifies data using the DD-classifier and a specified outsider treatment.

Usage

```
ddalpha.classify(ddalpha, objects, subset, outsider.method = NULL, use.convex = NULL)

## S3 method for class 'ddalpha'
predict(object, objects, subset, outsider.method = NULL, use.convex = NULL, ...)
```

Arguments

ddalpha, object	DDα-classifier (obtained by ddalpha.train).
objects	Matrix containing objects to be classified; each row is one d-dimensional object.
subset	an optional vector specifying a subset of observations to be classified.
outsider.method	Character string, name of a treatment to be used for outsiders; one of those trained by ddalpha.train. If the treatment was specified using the argument outsider.methods then use the name of the method.
use.convex	Logical variable indicating whether outsiders should be determined as the points not contained in any of the convex hulls of the classes from the training sample (TRUE) or those having zero depth w.r.t. each class from the training sample (FALSE). For depth = "zonoid" both values give the same result. If NULL the value specified in DDα-classifier (in ddalpha.train) is used.

... additional parameters are ignored

Details

Only one outsider treatment can be specified.

See Lange, Mosler and Mozharovskyi (2014) for details and additional information.

Value

List containing class labels, or character string "Ignored" for the outsiders if "Ignore" was specified as the outsider treating method.

```

`ddalpha.getErrorRateCV` *Test DD-Classifier*

Description

Performs a cross-validation procedure over the given data. On each step every `numchunks` observation is removed from the data, the DD-classifier is trained on these data and tested on the removed observations.

Usage

```
ddalpha.getErrorRateCV (data, numchunks = 10,  ...)
```

Arguments

`data`	Matrix containing training sample where each of n rows is one object of the training sample where first d entries are inputs and the last entry is output (class label).
`numchunks`	number of subsets of testing data. Equals to the number of times the classifier is trained.
`...`	additional parameters passed to `ddalpha.train`

Value

`errors`	the part of incorrectly classified data
`time`	the mean training time
`time_sd`	the standard deviation of training time

See Also

`ddalpha.train` to train the DDα-classifier, `ddalpha.classify` for classification using DDα-classifier, `ddalpha.test` to test the DD-classifier on particular learning and testing data, `ddalpha.getErrorRatePart` to perform a benchmark study of the DD-classifier on particular data.

Examples

```
# Generate a bivariate normal location-shift classification task
# containing 200 training objects and 200 to test with
class1 <- mvrnorm(150, c(0,0),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
class2 <- mvrnorm(150, c(2,2),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
propertyVars <- c(1:2)
classVar <- 3
data <- rbind(cbind(class1, rep(1, 150)), cbind(class2, rep(2, 150)))

# Train 1st DDalpha-classifier (default settings)
# and get the classification error rate
stat <- ddalpha.getErrorRateCV(data, numchunks = 5)
cat("1. Classification error rate (defaults): ",
    stat$error, ".\n", sep = "")

# Train 2nd DDalpha-classifier (zonoid depth, maximum Mahalanobis
# depth classifier with defaults as outsider treatment)
# and get the classification error rate
stat2 <- ddalpha.getErrorRateCV(data, depth = "zonoid",
                          outsider.methods = "depth.Mahalanobis")
cat("2. Classification error rate (depth.Mahalanobis): ",
    stat2$error, ".\n", sep = "")
```

---

ddalpha.getErrorRatePart

Test DD-Classifier

Description

Performs a benchmark procedure by partitioning the given data. On each of `times` steps `size` observations are removed from the data, the DD-classifier is trained on these data and tested on the removed observations.

Usage

```
ddalpha.getErrorRatePart(data, size = 0.3, times = 10,  ...)
```

Arguments

`data`	Matrix containing training sample where each of n rows is one object of the training sample where first d entries are inputs and the last entry is output (class label).
`size`	the excluded sequences size. Either an integer between 1 and n, or a fraction of data between 0 and 1.

times	the number of times the classifier is trained.
...	additional parameters passed to ddalpha.train

Value

errors	the part of incorrectly classified data (mean)
errors_sd	the standard deviation of errors
errors_vec	vector of errors
time	the mean training time
time_sd	the standard deviation of training time

```
# Generate a bivariate normal location-shift classification task
# containing 200 objects
class1 <- mvrnorm(100, c(0,0),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
class2 <- mvrnorm(100, c(2,2),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
propertyVars <- c(1:2)
classVar <- 3
data <- rbind(cbind(class1, rep(1, 100)), cbind(class2, rep(2, 100)))

# Train 1st DDalpha-classifier (default settings)
# and get the classification error rate
stat <- ddalpha.getErrorRatePart(data, size = 10, times = 10)
cat("1. Classification error rate (defaults): ",
    stat$error, ".\n", sep = "")

# Train 2nd DDalpha-classifier (zonoid depth, maximum Mahalanobis
# depth classifier with defaults as outsider treatment)
# and get the classification error rate
stat2 <- ddalpha.getErrorRatePart(data, depth = "zonoid",
                          outsider.methods = "depth.Mahalanobis", size = 0.2, times = 10)
cat("2. Classification error rate (depth.Mahalanobis): ",
    stat2$error, ".\n", sep = "")
```

`ddalpha.test` *Test DD-Classifier*

Description

Trains DD-classifier on the learning sequence of the data and tests it on the testing sequence.

Usage

```
ddalpha.test(learn, test, ...)
```

Arguments

`learn`	the learning sequence of the data. Matrix containing training sample where each of n rows is one object of the training sample where first d entries are inputs and the last entry is output (class label).
`test`	the testing sequence. Has the same format as `learn`
`...`	additional parameters passed to `ddalpha.train`

Value

`error`	the part of incorrectly classified data
`correct`	the number of correctly classified objects
`incorrect`	the number of incorrectly classified objects
`total`	the number of classified objects
`ignored`	the number of ignored objects (outside the convex hull of the learning data)
`n`	the number of objects in the testing sequence
`time`	training time

cat("2. Classification error rate (depth.Mahalanobis): ",
    stat2$error, ".\n", sep = "")
```

`ddalpha.train` *Train DD-Classifier*

Description

Trains the DD-classifier using a training sample according to given parameters. The DD-classifier is a non-parametric procedure that first transforms the training sample into the depth space calculating the depth of each point w.r.t each class (dimension of this space equals the number of classes in the training sample), and then constructs a separating rule in this depth space. If in the classification phase an object does not belong to the convex hull of at least one class (we mention such an object as an 'outsider'), it is mapped into the origin of the depth space and hence cannot be classified in the depth space. For these objects, after 'outsiderness' has been assured, an outsider treatment, i.e. a classification procedure functioning outside convex hulls of the classes is applied; it has to be trained too.

The current realization of the DD-classifier allows for several alternative outsider treatments; they involve different traditional classification methods, see 'Details' and 'Arguments' for parameters needed.

The function allows for classification with $q \geq 2$ classes, see `aggregation.method` in 'Arguments'.

Usage

```
ddalpha.train(formula, data, subset,
              depth = "halfspace",
              separator = "alpha",
              outsider.methods = "LDA",
```

```
                outsider.settings = NULL,
                aggregation.method = "majority",
                pretransform = NULL,
                use.convex = FALSE,
                seed = 0,
                ...)
```

Arguments

formula	an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model. If not found in data, the variables of the model are taken from environment.
data	Matrix or data.frame containing training sample where each of n rows is one object of the training sample where first d entries are inputs and the last entry is output (class label). A pre-calculated DD-plot may be used as data with depth="ddplot".
subset	an optional vector specifying a subset of observations to be used in training the classifier.
depth	Character string determining which depth notion to use; the default value is "halfspace". The list of the supported depths is given in section Depths. To use a custom depth, see topic Custom Methods. To use an outsider treatment only set depth = NULL.
separator	The method used for separation on the DD-plot; can be "alpha" (the default), "polynomial", "knnlm" or "maxD". See section Separators for the description of the separators and additional parameters. To use a custom separator, see topic Custom Methods.
outsider.methods	Vector of character strings each being a name of a basic outsider method for eventual classification; possible names are: "LDA" (the default), "QDA", "kNN", "kNNAff", "depth.Mahalanobis", "RandProp", "RandEqual" and "Ignore". Each method can be specified only once, replications are ignored. By specifying treatments in such a way only a basic treatment method can be chosen (by the name), and the default settings for each of the methods are applied, see 'Details'.
outsider.settings	List containing outsider treatments each described by a list of parameters including a name, see 'Details' and 'Examples'. Each method can be used multiply with (not necessarily) different parameters, just the name should be unique, entries with the repeating names are ignored.
aggregation.method	Character string determining which method to apply to aggregate binary classification results during multiclass classification; can be "majority" (the default) or "sequent". If "majority", $q(q-1)/2$ (with q being the number of classes in the training sample) binary classifiers are trained, the classification results are aggregated using the majority voting, where classes with larger proportions in the training sample (eventually with the earlier entries in the data) are preferred when tied. If "sequent", q binary 'one against all'-classifiers are trained and ties during the classification are resolved as before.

`pretransform` indicates if the data has to be scaled before the learning procedure. If the used depth method is affine-invariant and pretransform doesn't influence the result, the data won't be transformed (the parameter is ignored).

NULL applies no transformation to the data

"1Mom", "1MCD" the data is transformed with the common covariance matrix of the whole data

"NMom", "NMCD" the data is transformed w.r.t. each class using its covariance martix. The depths w.r.t. each class are calculated using the transformed data.
for the values `"1MCD"`, `"NMCD"` `covMcd` is used to calculate the covariance matrix, and the parameter `mah.parMcd` is used.

`use.convex` Logical variable indicating whether outsiders should be determined exactly, i.e. as the points not contained in any of the convex hulls of the classes from the training sample (`TRUE`), or those having zero depth w.r.t. each class from the training sample (`FALSE`). For `depth = "zonoid"` both values give the same result.

`seed` the random seed. The default value `seed=0` makes no changes.

`...` The parameters for the depth calculating and separation methods.

Details

Depths:

For `depth="ddplot"` the pre-calculated DD-plot shall be passed as `data`.

To use a custom depth, see topic `Custom Methods`.

To use an outsider treatment only set `depth = NULL`.

The following depths are supported:

`depth.halfspace` for calculation of the Tukey depth.

`depth.Mahalanobis` for calculation of Mahalanobis depth.

`depth.projection` for calculation of projection depth.

`depth.simplicial` for calculation of simplicial depth.

`depth.simplicialVolume` for calculation of simplicial volume depth.

`depth.spatial` for calculation of spatial depth.

`depth.zonoid` for calculation of zonoid depth.

The additional parameters are described in the corresponding topics.

Separators:

The separators classify data on the 2-dimensional space of a DD-plot built using the depths.

To use a custom separator, see topic `Custom Methods`.

alpha:
Trains the DDα-classifier (Lange, Mosler and Mozharovskyi, 2014; Mozharovskyi, Mosler and Lange, 2015). The DDα-classifier constructs a linear separating rule in the polynomial extension of the depth space with the α-procedure (Vasil'ev, 2003); maximum degree of the polynomial products is determined via cross-validation (in the depth space).
The additional parameters:

max.degree Maximum of the range of degrees of the polynomial depth space extension over which the α-procedure is to be cross-validated; can be 1, 2 or 3 (default).

num.chunks Number of chunks to split data into when cross-validating the α-procedure; should be > 0, and smaller than the total number of points in the two smallest classes when `aggregation.method = "majority"` and smaller than the total number of points in the training sample when `aggregation.method = "sequent"`. The default value is 10.

polynomial:
Trains the polynomial DD-classifier (Li, Cuesta-Albertos and Liu, 2012). The DD-classifier constructs a polynomial separating rule in the depth space; the degree of the polynomial is determined via cross-validation (in the depth space).
The additional parameters:

max.degree Maximum of the range of degrees of the polynomial over which the separator is to be cross-validated; can be in [1:10], the default value is 3.

num.chunks Number of chunks to split data into when cross-validating the separator; should be > 0, and smaller than the total number of points in the two smallest classes when `aggregation.method = "majority"` and smaller than the total number of points in the training sample when `aggregation.method = "sequent"`. The default value is 10.

knnlm:
Trains the k-nearest neighbours classifier in the depth space.
The additional parameters:

knnrange The maximal number of neighbours for kNN separation. The value is bounded by 2 and $n/2$.
`NULL` for the default value $10 * (n^{1/q}) + 1$, where n is the number of objects, q is the number of classes.
`"MAX"` for the maximum value $n/2$

maxD: The `maximum depth` separator classifies an object to the class that provides it the largest depth value.

Outsider treatment:

An outsider treatment is a supplementary classifier for data that lie outside the convex hulls of all q training classes. Available methods are: Linear Discriminant Analysis (referred to as "LDA"), see `lda`; k-Nearest-Neighbor Classifier ("kNN"), see `knn`, `knn.cv`; Affine-Invariant kNN ("kNNAff"), an affine-invariant version of the kNN, suited only for binary classification (some aggregation is used with multiple classes) and not accounting for ties (at all), but very fast by that; Maximum Mahalanobis Depth Classifier ("depth.Mahalanobis"), the outsider is referred to a class w.r.t. which it has the highest depth value scaled by (approximated) priors; Proportional Randomization ("RandProp"), the outsider is referred to a class randomly with probability equal to it (approximated) prior; Equal Randomization ("RandEqual"), the outsider is referred to a class randomly, chances for each class are equal; Ignoring ("Ignore"), the outsider is not classified, the string "Ignored" is returned instead.

An outsider treatment is specified by a list containing a name and parameters:

`name` is a character string, name of the outsider treatment to be freely specified; should be unique; is obligatory.

`method` is a character string, name of the method to use, can be `"LDA"`, `"kNN"`, `"kNNAff"`, `"depth.Mahalanobis"`, `"RandProp"`, `"RandEqual"` and `"Ignore"`; is obligatory.

priors is a numerical vector specifying prior probabilities of classes; class portions in the training sample are used by the default. priors is used in methods "LDA", "depth.Mahalanobis" and "RandProp".

knn.k is the number of the nearest neighbors taken into account; can be between 1 and the number of points in the training sample. Set to -1 (the default) to be determined by the leave-one-out cross-validation. knn.k is used in method "kNN".

knn.range is the upper bound on the range over which the leave-one-out cross-validation is performed (the lower bound is 1); can be between 2 and the number of points in the training sample -1. Set to -1 (the default) to be calculated automatically accounting for number of points and dimension. knn.range is used in method "kNN".

knnAff.methodAggregation is a character string specifying the aggregation technique for method "kNNAff"; works in the same way as the function argument aggregation.method. knnAff.methodAggregation is used in method "kNNAff".

knnAff.k is the number of the nearest neighbors taken into account; should be at least 1 and up to the number of points in the training sample when knnAff.methodAggregation = "sequent", and up to the total number of points in the training sample when knnAff.methodAggregation = "majority". Set to -1 (the default) to be determined by the leave-one-out cross-validation. knnAff.k is used in method "kNNAff".

knnAff.range is the upper bound on the range over which the leave-one-out cross-validation is performed (the lower bound is 1); should be > 1 and smaller than the total number of points in the two smallest classes when knnAff.methodAggregation = "majority", and > 1 and smaller than the total number of points in the training sample when knnAff.methodAggregation = "sequent". Set to -1 to be calculated automatically accounting for number of points and dimension. knnAff.range is used in method "kNNAff".

mah.estimate is a character string specifying which estimates to use when calculating the Mahalanobis depth; can be "moment" or "MCD", determining whether traditional moment or Minimum Covariance Determinant (MCD) (see covMcd) estimates for mean and covariance are used. mah.estimate is used in method "depth.Mahalanobis".

mcd.alpha is the value of the argument alpha for the function covMcd; is used in method "depth.Mahalanobis" when mah.estimate = "MCD".

Value

Trained DDα-classifier containing following - rather informative - fields:

num.points	Total number of points in the training sample.
dimension	Dimension of the original space.
depth	Character string determining which depth notion to use.
methodAggregation	Character string determining which method to apply to aggregate binary classification results.
num.chunks	Number of chunks data has been split into when cross-validating the α-procedure.
num.directions	Number of directions used for approximating the Tukey depth (when it is used).
use.convex	Logical variable indicating whether outsiders should be determined exactly when classifying.
max.degree	Maximum of the range of degrees of the polynomial depth space extension over which the α-procedure has been cross-validated.

`patterns` Classes of the training sample.

`num.classifiers`
Number of binary classifiers trained.

`outsider.methods`
Treatments to be used to classify outsiders.

`ddalphaf.classify` *Classify using Functional DD-Classifier*

Description

Classifies data using the functional DD-classifier.

Usage

```
ddalphaf.classify(ddalphaf, objectsf, subset, ...)

## S3 method for class 'ddalphaf'
predict(object, objectsf, subset, ...)
```

Arguments

`ddalphaf, object`	Functional DD-classifier (obtained by `ddalphaf.train`).
`objectsf`	list containing lists (functions) of two vectors of equal length, named "args" and "vals": arguments sorted in ascending order and corresponding them values respectively
`subset`	an optional vector specifying a subset of observations to be classified.
`...`	additional parameters, passed to the classifier, selected with parameter `classifier.type` in `ddalphaf.train`.

Value

List containing class labels.

References

Mozharovskyi, P. (2015). *Contributions to Depth-based Classification and Computation of the Tukey Depth*. Verlag Dr. Kovac (Hamburg).

See Also

`ddalphaf.train` to train the functional DDα-classifier.

Examples

```
## Not run:
## load the Growth dataset
dataf = dataf.growth()

learn = c(head(dataf$dataf, 49), tail(dataf$dataf, 34))
labels= c(head(dataf$labels, 49), tail(dataf$labels, 34))
test  = tail(head(dataf$dataf, 59), 10)    # elements 50:59. 5 girls, 5 boys

c = ddalphaf.train (learn, labels, classifier.type = "ddalpha")

classified = ddalphaf.classify(c, test)

print(unlist(classified))

## End(Not run)
```

`ddalphaf.getErrorRateCV` *Test Functional DD-Classifier*

Description

Performs a cross-validation procedure over the given data. On each step every `numchunks` observation is removed from the data, the functional DD-classifier is trained on these data and tested on the removed observations.

Usage

```
ddalphaf.getErrorRateCV (dataf, labels, numchunks = 10, disc.type = c("LS", "comp"),  ...)
```

Arguments

`dataf`	list containing lists (functions) of two vectors of equal length, named "args" and "vals": arguments sorted in ascending order and corresponding them values respectively
`labels`	list of output labels of the functional observations
`numchunks`	number of subsets of testing data. Equals to the number of times the classifier is trained.
`disc.type`	type of the used discretization scheme. "LS" for `ddalphaf.train`, "comp" for for `compclassf.train`
`...`	additional parameters passed to `ddalphaf.train`

Value

errors	the part of incorrectly classified data
time	the mean training time
time_sd	the standard deviation of training time

See Also

ddalphaf.train to train the functional DDα-classifier, ddalphaf.classify for classification using functional DDα-classifier, ddalphaf.test to test the functional DD-classifier on particular learning and testing data, ddalphaf.getErrorRatePart to perform a benchmark study of the functional DD-classifier on particular data.

Examples

```
# load the fdata
df = dataf.growth()

stat <- ddalphaf.getErrorRateCV(dataf = df$dataf, labels = df$labels,
                                numchunks = 5,
                                adc.args = list(instance = "avr",
                                                numFcn = 2,
                                                numDer = 2))

cat("Classification error rate: ", stat$errors, ".\n", sep = "")
```

---

ddalphaf.getErrorRatePart

Test Functional DD-Classifier

Description

Performs a benchmark procedure by partitioning the given data. On each of times steps size observations are removed from the data, the functional DD-classifier is trained on these data and tested on the removed observations.

Usage

```
ddalphaf.getErrorRatePart(dataf, labels, size = 0.3, times = 10,
                          disc.type = c("LS", "comp"),  ...)
```

Arguments

dataf	list containing lists (functions) of two vectors of equal length, named "args" and "vals": arguments sorted in ascending order and corresponding them values respectively
labels	list of output labels of the functional observations
size	the excluded sequences size. Either an integer between 1 and n, or a fraction of data between 0 and 1.
times	the number of times the classifier is trained.
disc.type	type of the used discretization scheme. "LS" for ddalphaf.train, "comp" for for compclassf.train
...	additional parameters passed to ddalphaf.train

Value

errors	the part of incorrectly classified data (mean)
errors_sd	the standard deviation of errors
errors_vec	vector of errors
time	the mean training time
time_sd	the standard deviation of training time

Examples

```
# load the fdata
df = dataf.growth()

stat <- ddalphaf.getErrorRatePart(dataf = df$dataf, labels = df$labels,
                          size = 0.3, times = 5,
                          adc.args = list(instance = "avr",
                                          numFcn = 2,
                                          numDer = 2))

cat("Classification error rate: ", stat$errors, ".\n", sep = "")
```

`ddalphaf.test` *Test Functional DD-Classifier*

Description

Trains functional DD-classifier on the learning sequence of the data and tests it on the testing sequence.

Usage

```
ddalphaf.test(learn, learnlabels, test, testlabels, disc.type = c("LS", "comp"), ...)
```

Arguments

`learn`	list containing lists (functions) of two vectors of equal length, named "args" and "vals": arguments sorted in ascending order and corresponding them values respectively
`learnlabels`	list of output labels of the functional observations
`test`	the testing sequence. Has the same format as `learn`
`disc.type`	type of the used discretization scheme. "LS" for `ddalphaf.train`, "comp" for for `compclassf.train`
`testlabels`	list of output labels of the functinal observations
`...`	additional parameters passed to `ddalphaf.train`

Value

`error`	the part of incorrectly classified data
`correct`	the number of correctly classified objects
`incorrect`	the number of incorrectly classified objects
`total`	the number of classified objects
`ignored`	the number of ignored objects (outside the convex hull of the learning data)
`n`	the number of objects in the testing sequence
`time`	training time

See Also

`ddalphaf.train` to train the functional DDα-classifier, `ddalphaf.classify` for classification using functonal DDα-classifier, `ddalphaf.getErrorRateCV` and `ddalphaf.getErrorRatePart` to get error rate of the functional DD-classifier on particular data.

Examples

```
# load the fdata
df = dataf.growth()

samp = c(35:70)

ddalphaf.test(learn = df$dataf[-samp], learnlabels = df$labels[-samp],
              test =  df$dataf[samp],  testlabels =  df$labels[samp],
              adc.args = list(instance = "avr",
                              numFcn = 2,
                              numDer = 2))
```

`ddalphaf.train` *Functional DD-Classifier*

Description

Trains the functional DD-classifier

Usage

```
ddalphaf.train(dataf, labels, subset,
                adc.args = list(instance = "avr",
                                numFcn = -1,
                                numDer = -1),
             classifier.type = c("ddalpha", "maxdepth", "knnaff", "lda", "qda"),
                cv.complete = FALSE,
                maxNumIntervals = min(25, ceiling(length(dataf[[1]]$args)/2)),
                seed = 0,
                ...)
```

Arguments

`dataf`	list containing lists (functions) of two vectors of equal length, named "args" and "vals": arguments sorted in ascending order and corresponding them values respectively
`labels`	list of output labels of the functional observations
`subset`	an optional vector specifying a subset of observations to be used in training the classifier.
`adc.args`	Represents a function sample as a multidimensional (dimension=`"numFcn"+"numDer"`) one averaging (`instance = "avr"`) or evaluating (`instance = "val"`) for that each function and it derivative on `"numFcn"` (resp. `"numDer"`) equal nonoverlapping covering intervals First two named `"args"` and `"vals"` are arguments sorted in ascending order and having same bounds for all functions and corresponding them values respectively

instance type of discretizing the functions:
"avr" - by averaging over intervals of the same length
"val" - by taking values on equally-spaced grid

numFcn number of function intervals

numDer number of first-derivative intervals

Set `numFcn` and `numDer` to -1 to apply cross-validation.

Set `adc.args` to a list of "adc.args" objects to cross-validate only over these values.

`classifier.type`
the classifier which is used on the transformed space. The default value is 'ddalpha'.

`cv.complete` T: apply complete cross-validation
F: restrict cross-validation by Vapnik-Chervonenkis bound

`maxNumIntervals`
maximal number of intervals for cross-validation (max(numFcn + numDer) = maxNumIntervals)

`seed` the random seed. The default value `seed=0` makes no changes.

`...` additional parameters, passed to the classifier, selected with parameter `classifier.type`.

Details

The functional DD-classifier is fast nonparametric procedure for classifying functional data. It consists of a two-step transformation of the original data plus a classifier operating on a low-dimensional hypercube. The functional data are first mapped into a finite-dimensional location-slope space and then transformed by a multivariate depth function into the DD-plot, which is a subset of the unit hypercube. This transformation yields a new notion of depth for functional data. Three alternative depth functions are employed for this, as well as two rules for the final classification. The resulting classifier is cross-validated over a small range of parameters only, which is restricted by a Vapnik-Cervonenkis bound. The entire methodology does not involve smoothing techniques, is completely nonparametric and allows to achieve Bayes optimality under standard distributional settings. It is robust and efficiently computable.

Value

Trained functional DD-classifier

depth. *Calculate Depth*

Description

Calculates the depth of points w.r.t. a multivariate data set.

The detailed descriptions are found in the corresponding topics.

Usage

```
depth.(x, data, notion, ...)
```

```
## beta-skeleton depth
# depth.betaSkeleton(x, data, beta = 2, distance = "Lp", Lp.p = 2,
#                    mah.estimate = "moment", mah.parMcd = 0.75)

## Tukey depth
# depth.halfspace(x, data, exact, method, num.directions = 1000, seed = 0)

## L2-depth
# depth.L2(x, data, mah.estimate = "moment", mah.parMcd = 0.75)

## Mahalanobis depth
# depth.Mahalanobis(x, data, mah.estimate = "moment", mah.parMcd = 0.75)

## projection depth
# depth.projection(x, data, method = "random", num.directions = 1000)

## simplicial depth
# depth.simplicial(x, data, exact = F, k = 0.05, seed = 0)

## simplicial volume depth
# depth.simplicialVolume(x, data, exact = F, k = 0.05, seed = 0)

## spatial depth
# depth.spatial(x, data)

## zonoid depth
# depth.zonoid(x, data)

## potential
# depth.potential (x, data, pretransform = "1Mom",
#             kernel = "GKernel", kernel.bandwidth = NULL, mah.parMcd = 0.75)

## convex hull peeling depth
# depth.qhpeeling(x, data)
```

Arguments

x	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as data.
data	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.
notion	The name of the depth notion (shall also work with a user-defined depth function named "depth.<name>").
...	Additional parameters passed to the depth functions.

Value

Numerical vector of depths, one for each row in x; or one depth value if x is a numerical vector.

```
# 5-dimensional normal distribution
data <- mvrnorm(1000, rep(0, 5),
                matrix(c(1, 0, 0, 0, 0,
                         0, 2, 0, 0, 0,
                         0, 0, 3, 0, 0,
                         0, 0, 0, 2, 0,
                         0, 0, 0, 0, 1),
                nrow = 5))
x <- mvrnorm(10, rep(1, 5),
             matrix(c(1, 0, 0, 0, 0,
                      0, 1, 0, 0, 0,
                      0, 0, 1, 0, 0,
                      0, 0, 0, 1, 0,
                      0, 0, 0, 0, 1),
             nrow = 5))

depths <- depth.(x, data, notion = "zonoid")
cat("Depths: ", depths, "\n")
```

depth.betaSkeleton *Calculate Beta-Skeleton Depth*

Description

Calculates the beta-skeleton depth of points w.r.t. a multivariate data set.

Usage

```
depth.betaSkeleton(x, data, beta = 2, distance = "Lp", Lp.p = 2,
                   mah.estimate = "moment", mah.parMcd = 0.75)
```

Arguments

x	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as data.
data	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.
beta	The paremeter defining the positionning of the balls' centers, see Yang and Modarres (2017) for details. By default (together with other arguments) equals 2, which corresponds to the lens depth, see Liu and Modarres (2011).
distance	A character string defining the distance to be used for determining inclusion of a point into the lens (influence region), see Yang and Modarres (2017) for details. Possibilities are "Lp" for the Lp-metric (default) or "Mahalanobis" for the Mahalanobis distance adjustment.
Lp.p	A non-negative number defining the distance's power equal 2 by default (Euclidean distance); is used only when distance = "Lp".
mah.estimate	A character string specifying which estimates to use when calculating sample covariance matrix; can be "none", "moment" or "MCD", determining whether traditional moment or Minimum Covariance Determinant (MCD) (see covMcd) estimates for mean and covariance are used. By default "moment" is used. Is used only when distance = "Mahalanobis".
mah.parMcd	The value of the argument alpha for the function covMcd; is used when distance = "Mahalanobis" and mah.estimate = "MCD".

Details

Calculates the beta-skeleton depth, see Yang and Modarres (2017). Its particular case, lens depth, see Liu and Modarres (2011), is obtained when beta = 2, distance = "Lp" and Lp.p = 2 (default settings). For tne example of the lens depth, the depth of an observation x is calculated as the portion of lens containing x, with lens being an intersection of two closed balls centered at two sample's points each having radius equal to the distance between these two points.

Value

Numerical vector of depths, one for each row in x; or one depth value if x is a numerical vector.

depths <- depth.betaSkeleton(x, data)
cat("Depths:", depths, "\n")
```

depth.contours *Depth Contours*

Description

Builds the data depth contours for 2-dimensional data.

Usage

```
depth.contours(data, depth,
               main = "", xlab="", ylab = "",
               drawplot = T, frequency=100, levels = 10,
               col = "red",
               ...)
```

Arguments

data	2-dimensional numeric data frame or matrix
depth	the name of the depth function. The list of the supported depths and described in the topic depth..
main	an overall title for the plot: see title
xlab, ylab	labels of the axes
drawplot	if set to false, the contours are built on the existing plot.
frequency	number of points on each direction, x and y. Impacts the smoothness of the contours.
levels	numeric vector of levels at which to draw contour lines. If the vector contains only ONE element, the levels are generated automatically as seq(0, max(depth), length.out = level
col	color, used to draw points and contours
...	additional parameters passed to the depth functions and to plot

See Also

depth., depth.contours.ddalpha, depth.graph.

Examples

```
## Not run:

par(mfrow = c(2,2))
data(hemophilia)

depth.contours(hemophilia[,1:2], depth = "none", main = "data")

for (depth in c("zonoid", "Mahalanobis", "projection", "spatial")){
  depth.contours(hemophilia[,1:2], depth = depth, main = depth)
```

```
}

for (depth in c("halfspace", "simplicial", "simplicialVolume")){
  depth.contours(hemophilia[,1:2], depth = depth, main = depth, exact = T)
}

## End(Not run)
```

`depth.contours.ddalpha` *Depth Contours*

Description

Builds the data depth contours for multiclass 2-dimensional data using the trained classifier. Also accessible from `plot.ddalpha`.

Usage

```
depth.contours.ddalpha(ddalpha,
              main = "", xlab="", ylab = "",
              drawplot = T, frequency=100, levels = 10, drawsep = T, ...)
```

Arguments

`ddalpha`	DDα-classifier (obtained by `ddalpha.train`).
`main`	an overall title for the plot: see `title`
`xlab, ylab`	labels of the axes
`drawplot`	if set to false, the contours are built on the existing plot.
`frequency`	number of points on each direction, x and y. Impacts the smoothness of the contours.
`levels`	numeric vector of levels at which to draw contour lines. If the vector contains only ONE element, the levels are generated automatically as `seq(0, max(depth), length.out = level`
`drawsep`	draws the separation on the DD-plot (currently for 2 classes and not for knn)
`...`	additional parameters passed to the depth functions and to `plot`

See Also

`depth.`, `depth.contours`, `depth.graph`.

Examples

```
## Not run:

par(mfrow = c(2,2))

ddalpha = ddalpha.train(hemophilia, depth = "none")
depth.contours.ddalpha(ddalpha, main = "data")

for (depth in c("zonoid", "Mahalanobis", "projection", "spatial")){
  ddalpha = ddalpha.train(hemophilia, depth = depth)
  depth.contours.ddalpha(ddalpha, main = depth)
}

for (depth in c("halfspace", "simplicial", "simplicialVolume")){
  ddalpha = ddalpha.train(hemophilia, depth = depth, exact = T)
  depth.contours.ddalpha(ddalpha, main = depth)
}

## End(Not run)
```

---

depth.graph *Depth Graph*

Description

Builds the data depth graphs for 2-dimensional data. The graph is built using persp.

Usage

```
depth.graph(data,
  depth_f = c("halfspace", "Mahalanobis", "projection", "simplicial",
              "simplicialVolume", "spatial", "zonoid", "none"),
  apoint = NULL,
  main = depth_f,
  xlim = c(min(data[, 1]), max(data[, 1])),
  ylim = c(min(data[, 2]), max(data[, 2])),
  zlim = c(0, max(z)),
  xnum = 250,
  ynum = 250,
  theta=15, phi=60,
  bold = F,
  ...)
```

Arguments

data	2-dimensional numeric data frame or matrix
depth_f	the name of the depth function. The list of the supported depths and described in the topic depth..
apoint	a 2-dimensional point which is shown in black color.
main	an overall title for the plot: see title
xlim, ylim, zlim	numeric vectors of length 2, giving the x, y and z coordinates ranges: see plot.window
xnum, ynum	number of points on each direction, x and y. Impacts the smoothness of the surface.
theta, phi	rotation angles
bold	draws bold points
...	additional parameters passed to persp

See Also

depth.

## End(Not run)
```

---

depth.halfspace *Calculate Halfspace Depth*

Description

Calculates the exact or random Tukey (=halfspace, location) depth (Tukey, 1975) of points w.r.t. a multivariate data set.

Usage

```
depth.halfspace(x, data, exact, method, num.directions = 1000, seed = 0)
```

Arguments

x	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as data.
data	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.
exact	The type of the used method. The default is exact=F, which leads to approximate computation of the Tukey depth. For exact=F, method="Sunif.1D" is used by default. If exact=T, the Tukey depth is computed exactly, with method="recursive" by default.
method	For exact=F, if method="Sunif.1D" (by default), the Tukey depth is computed approximately by being minimized over univariate projections (see Details below). For exact=T, the Tukey depth is calculated as the minimum over all combinations of k points from data (see Details below). In this case parameter method specifies k, with possible values 1 for method="recursive" (by default), $d-2$ for method="plane", $d-1$ for method="line". The name of the method may be given as well as just parameter exact, in which case the default method will be used.
num.directions	Number of random directions to be generated (for method="Sunif.1D"). The algorithmic complexity is linear in the number of observations in data, given the number of directions.
seed	The random seed. The default value seed=0 makes no changes (for method="Sunif.1D").

Details

For exact=F, if method="Sunif.1D", the Tukey depth is computed approximately using the random Tukey depth method proposed by Cuesta-Albertos and Nieto-Reyes (2008). Here the depth is determined as the minimum univariate Tukey depth of the - on lines in several directions - projected data. The directions are distributed uniformly on the $(d-1)$-sphere; the same direction set is used for all points.

For exact=T, the Tukey depth is computed exactly as the minimum of the sum of the depths in two orthogonal complementary affine subspaces, which dimensions add to d: one of the subspaces (combinatorial) is the k-dimensional hyperplane through (a point from) x and k points from data, another one is its orthogonal complement (see Dyckerhoff and Mozharovskyi, 2016 for the detailed description of the algorithmic framework). The algorithm then minimizes the depth over all combinations of k points, in which the depth in the orthogonal complements is computed using an exact algorithm. In this case, parameter method specifies the dimensionality k of the combinatorial space. The implemented (reasonable) algorithms (and corresponding names) are: $k = 1$ (or method="recursive"), $k = d-2$ (or method="plane"), and $k = d-1$ (or method="line").

Value

Numerical vector of depths, one for each row in x; or one depth value if x is a numerical vector.

`depth.L2` *Calculate L2-Depth*

Description

Calculates the L2-depth of points w.r.t. a multivariate data set.

Usage

```
depth.L2(x, data, mah.estimate = "moment", mah.parMcd = 0.75)
```

Arguments

`x`	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as `data`.
`data`	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.
`mah.estimate`	is a character string specifying which estimates to use when calculating sample covariance matrix; can be `"none"`, `"moment"` or `"MCD"`, determining whether traditional moment or Minimum Covariance Determinant (MCD) (see `covMcd`) estimates for mean and covariance are used. By default `"moment"` is used. With `"none"` the non-affine invariant version of the L2-depth is calculated
`mah.parMcd`	is the value of the argument `alpha` for the function `covMcd`; is used when `mah.estimate = "MCD"`.

Details

Calculates L2-depth (Mosler, 2013). L2-depth is a based on the oultyingness distance calculated as the average L2-distance from (a row of) `x` to each point in `data`.

Value

Numerical vector of depths, one for each row in `x`; or one depth value if `x` is a numerical vector.

             nrow = 5))

depths <- depth.spatial(x, data)
cat("Depths:", depths, "\n")
```

---

depth.Mahalanobis *Calculate Mahalanobis Depth*

Description

Calculates the Mahalanobis depth of points w.r.t. a multivariate data set.

Usage

```
depth.Mahalanobis(x, data, mah.estimate = "moment", mah.parMcd = 0.75)
```

Arguments

x	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as data.
data	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.
mah.estimate	is a character string specifying which estimates to use when calculating the Mahalanobis depth; can be "moment" or "MCD", determining whether traditional moment or Minimum Covariance Determinant (MCD) (see covMcd) estimates for mean and covariance are used. By default "moment" is used.
mah.parMcd	is the value of the argument alpha for the function covMcd; is used when mah.estimate = "MCD".

Details

Calculates Mahalanobis depth. Mahalanobis depth is based on an outlyingness measure (Zuo & Serfling, 2000), *viz.* the Mahalanobis distance between the given point and the center of the data (Mahalanobis, 1936).

Moment estimates may be used i.e. traditional *mean* and *covariance matrix*, the corresponding depth may be sensitive to outliers. A more robust depth is obtained with *minimum volume ellipsoid* (MVE) or *minimum covariance determinant* (MCD) estimators, see Rousseeuw & Leroy (1987) and Lopuhaa & Rousseeuw (1991).

Value

Numerical vector of depths, one for each row in x; or one depth value if x is a numerical vector.

cat("Depths MCD: ", depths, "\n")
```

---

depth.potential *Calculate Potential of the Data*

Description

Calculate the potential of the points w.r.t. a multivariate data set. The potential is the kernel-estimated density multiplied by the prior probability of a class. Different from the data depths, a density estimate measures at a given point how much mass is located around it.

Usage

```
depth.potential (x, data, pretransform = "1Mom",
                 kernel = "GKernel", kernel.bandwidth = NULL, mah.parMcd = 0.75)
```

Arguments

x	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as data.

data	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.
pretransform	The method of data scaling. NULL to use the original data, 1Mom or NMom for scaling using data moments, 1MCD or NMCD for scaling using robust data moments (Minimum Covariance Determinant (MCD)).
kernel	"EDKernel" for the kernel of type 1/(1+kernel.bandwidth*EuclidianDistance2(x, y)), "GKernel" [default and recommended] for the simple Gaussian kernel, "EKernel" exponential kernel: exp(-kernel.bandwidth*EuclidianDistance(x, y)), "VarGKernel" variable Gaussian kernel, where kernel.bandwidth is proportional to the depth.zonoid of a point.
kernel.bandwidth	the single bandwidth parameter of the kernel. If NULL - the Scott's rule of thumb is used.
mah.parMcd	is the value of the argument alpha for the function covMcd; is used when pretransform = "*MCD".

Details

The potential is the kernel-estimated density multiplied by the prior probability of a class. The kernel bandwidth matrix is decomposed into two parts, one of which describes the form of the data, and the other the width of the kernel. Then the first part is used to transform the data using the moments, while the second is employed as a parameter of the kernel and tuned to achieve the best separation. For details see Pokotylo and Mosler (2015).

Value

Numerical vector of potentials, one for each row in x; or one potential value if x is a numerical vector.

cat("Potentials: ", pot, "\n")
```

---

depth.projection *Calculate Projection Depth*

Description

Calculates the projection depth of points w.r.t. a multivariate data set.

Usage

```
depth.projection(x, data, method = "random", num.directions = 1000, seed = 0)
```

Arguments

x	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as data.
data	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.
method	to be used in calculations. "random" Here the depth is determined as the minimum univariate depth of the data projected on lines in several directions. The directions are distributed uniformly on the $(d-1)$-sphere; the same direction set is used for all points.

	`"linearize"` The Nelder-Mead method for function minimization, taken from Olsson, Journal of Quality Technology, 1974, 6, 56.
`num.directions`	Number of random directions to be generated for `method = "random"`. With the growth of n the complexity grows linearly for the same number of directions.
`seed`	the random seed. The default value `seed=0` makes no changes.

Details

Calculates projection depth. Projection depth, similar to Mahalanobis depth, is based on a measure of outlyingness, used by Stahel (1981) and Donoho (1982), and has been first formulated by Liu (1992). The worst case outlyingness is obtained by maximizing an outlyingness measure over all univariate projections. In practice most often *median*, and *median absolute deviation from the median* (MAD), are used as they are robust measures.

Value

Numerical vector of depths, one for each row in `x`; or one depth value if `x` is a numerical vector.

Author(s)

R-codes for the "linearize" method were written by Subhajit Dutta.

depth.qhpeeling *Calculate Convex Hull Peeling Depth*

Description

Calculates the convex hull peeling depth of points w.r.t. a multivariate data set.

Usage

```
depth.qhpeeling(x, data)
```

Arguments

x	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as data.
data	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.

Details

Calculates the convex hull peeling depth (Eddy, 1982; see also Cascos, 2009).

Value

Numerical vector of depths, one for each row in x; or one depth value if x is a numerical vector. Each depth value equals the number of the convex hulls to be peeled from data so that (the corresponding row of) x is not contained in the convex hull of the rest of the data; the depths are normalized by the number of points in data.

depth.sample *Fast Depth Computation for Univariate and Bivariate Random Samples*

Description

Faster implementation of the halfspace and the simplicial depth. Computes the depth of a whole random sample of a univariate or a bivariate data in one run.

Usage

```
depth.sample(A, B)
```

Arguments

A	Univariate or bivariate points whose depth is computed, represented by a matrix of size m*2. m stands for the number of points, d is 1 for univariate and 2 for bivariate data.
B	Random sample points with respect to which the depth of A is computed. B is represented by a matrix of size n*2, where n is the sample size.

Details

The function returns vectors of sample halfspace and simplicial depth values.

Value

Vector of length m of depth halfspace depth values is returned.

Author(s)

Stanislav Nagy, <nagy at karlin.mff.cuni.cz>

```

`depth.simplicial` *Calculate Simplicial Depth*

Description

Calculates the simplicial depth of points w.r.t. a multivariate data set.

Usage

```
depth.simplicial(x, data, exact = F, k = 0.05, seed = 0)
```

Arguments

`x`	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as `data`.
`data`	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.
`exact`	`exact=F` (by default) implies the approximative algorithm, considering `k` simplices, `exact=T` implies the exact algorithm.
`k`	Number ($k > 1$) or portion (if $0 < k < 1$) of simplices that are considered if `exact=F`. If $k > 1$, then the algorithmic complexity is polynomial in d but is independent of the number of observations in `data`, given k. If $0 < k < 1$, then the algorithmic complexity is exponential in the number of observations in `data`, but the calculation precision stays approximately the same.
`seed`	the random seed. The default value `seed=0` makes no changes.

Details

Calculates simplicial depth. Simplicial depth is counted as a probability that a point lies in a simplex, built on $d + 1$ data points.

Value

Numerical vector of depths, one for each row in `x`; or one depth value if `x` is a numerical vector.

depth.simplicialVolume

Calculate Simplicial Volume Depth

Description

Calculates the simpicial volume depth of points w.r.t. a multivariate data set.

Usage

```
depth.simplicialVolume(x, data, exact = F, k = 0.05, seed = 0)
```

Arguments

x	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as data.
data	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.
exact	exact=F (by default) implies the approximative algorithm, considering k simplices, exact=T implies the exact algorithm.
k	Number ($k > 1$) or portion (if $0 < k < 1$) of simplices that are considered if exact=F. If $k > 1$, then the algorithmic complexity is polynomial in d but is independent of the number of observations in data, given k. If $0 < k < 1$, then the algorithmic complexity is exponential in the number of observations in data, but the calculation precision stays approximately the same.
seed	The random seed. The default value seed=0 makes no changes.

Details

Calculates Oja depth (also: Simplicial volume depth). At first the Oja outlyingness function O(x,data) is calculated as the average of the volumes of simplices built on d data points and the measurement point x (Oja, 1983).

Zuo and Serfling (2000) proposed Oja depth based on the Oja outlyingness function as 1/(1 + O(x,data)/S), where S is a square root of the determinant of cov(data), which makes the depth function affine-invariant.

Value

Numerical vector of depths, one for each row in x; or one depth value if x is a numerical vector.

depth.space. *Calculate Depth Space using the Given Depth*

Description

Calculates the representation of the training classes in depth space.

The detailed descriptions are found in the corresponding topics.

Usage

```
depth.space.(data, cardinalities, notion, ...)

## Mahalanobis depth
# depth.space.Mahalanobis(data, cardinalities, mah.estimate = "moment", mah.parMcd = 0.75)

## projection depth
# depth.space.projection(data, cardinalities, method = "random", num.directions = 1000)

## Tukey depth
# depth.space.halfspace(data, cardinalities, exact, alg, num.directions = 1000)

## spatial depth
# depth.space.spatial(data, cardinalities)

## zonoid depth
# depth.space.zonoid(data, cardinalities)
```

```
# Potential
# depth.space.potential(data, cardinalities, pretransform = "NMom",
#            kernel = "GKernel", kernel.bandwidth = NULL, mah.parMcd = 0.75)
```

Arguments

data	Matrix containing training sample where each row is a d-dimensional object, and objects of each class are kept together so that the matrix can be thought of as containing blocks of objects representing classes.
cardinalities	Numerical vector of cardinalities of each class in data, each entry corresponds to one class.
notion	The name of the depth notion (shall also work with Custom Methods).
...	Additional parameters passed to the depth functions.

Value

Matrix of objects, each object (row) is represented via its depths (columns) w.r.t. each of the classes of the training sample; order of the classes in columns corresponds to the one in the argument cardinalities.

Examples

```
# Generate a bivariate normal location-shift classification task
# containing 20 training objects
class1 <- mvrnorm(10, c(0,0),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
class2 <- mvrnorm(10, c(2,2),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
data <- rbind(class1, class2)
# Get depth space using zonoid depth
depth.space.(data, c(10, 10), notion = "zonoid")
```

`depth.space.halfspace` *Calculate Depth Space using Halfspace Depth*

Description

Calculates the representation of the training classes in depth space using the halfspace depth.

Usage

```
depth.space.halfspace(data, cardinalities, exact, method, num.directions = 1000, seed = 0)
```

Arguments

`data`	Matrix containing training sample where each row is a d-dimensional object, and objects of each class are kept together so that the matrix can be thought of as containing blocks of objects representing classes.
`cardinalities`	Numerical vector of cardinalities of each class in `data`, each entry corresponds to one class.
`exact`	The type of the used method. The default is `exact=F`, which leads to approximate computation of the halfspace depth. For `exact=F`, `method="Sunif.1D"` is used by default. If `exact=T`, the halfspace depth is computed exactly, with `method="recursive"` by default.
`method`	For `exact=F`, if `method="Sunif.1D"` (by default), the halfspace depth is computed approximately by being minimized over univariate projections (see details). For `exact=T`, the halfspace depth is calculated as the minimum over all combinations of k points from `data` (see details). In this case parameter `method` specifies k, with possible values 1 for `method="recursive"` (by default), $d-2$ for `method="plane"`, $d-1$ for `method="line"`. The name of the method may be given as well as just parameter `exact`, in which case the default method will be used.
`num.directions`	Number of random directions to be generated. As the same direction set is used for all observations, the algorithmic complexity of calculating the depth of each single point in `data` is logarithmic in the number of observations in `data`, given the number of directions, see Mozharovskyi et al. (2015), Section 2.3 for discussion.
`seed`	The random seed. The default value `seed=0` makes no changes.

Details

The depth representation is calculated in the same way as in `depth.halfspace`, see References below for more information and details.

Value

Matrix of objects, each object (row) is represented via its depths (columns) w.r.t. each of the classes of the training sample; order of the classes in columns corresponds to the one in the argument `cardinalities`.

```

`depth.space.Mahalanobis` *Calculate Depth Space using Mahalanobis Depth*

Description

Calculates the representation of the training classes in depth space using Mahalanobis depth.

Usage

```
depth.space.Mahalanobis(data, cardinalities, mah.estimate = "moment", mah.parMcd = 0.75)
```

Arguments

`data`	Matrix containing training sample where each row is a d-dimensional object, and objects of each class are kept together so that the matrix can be thought of as containing blocks of objects representing classes.
`cardinalities`	Numerical vector of cardinalities of each class in `data`, each entry corresponds to one class.
`mah.estimate`	is a character string specifying which estimates to use when calculating the Mahalanobis depth; can be `"moment"` or `"MCD"`, determining whether traditional moment or Minimum Covariance Determinant (MCD) (see `covMcd`) estimates for mean and covariance are used. By default `"moment"` is used.
`mah.parMcd`	is the value of the argument `alpha` for the function `covMcd`; is used when `mah.estimate = "MCD"`.

Details

The depth representation is calculated in the same way as in `depth.Mahalanobis`, see 'References' for more information and details.

Value

Matrix of objects, each object (row) is represented via its depths (columns) w.r.t. each of the classes of the training sample; order of the classes in columns corresponds to the one in the argument `cardinalities`.

cardinalities = c(sum(data$gr == "normal"), sum(data$gr == "carrier"))
depth.space.Mahalanobis(data[,1:2], cardinalities)
```

---

depth.space.potential *Calculate Potential Space*

Description

Calculates the representation of the training classes in potential space.

Usage

```
depth.space.potential(data, cardinalities, pretransform = "NMom",
            kernel = "GKernel", kernel.bandwidth = NULL, mah.parMcd = 0.75)
```

Arguments

`data`	Matrix containing training sample where each row is a d-dimensional object, and objects of each class are kept together so that the matrix can be thought of as containing blocks of objects representing classes.
`cardinalities`	Numerical vector of cardinalities of each class in `data`, each entry corresponds to one class.

`pretransform` The method of data scaling.

`NULL` to use the original data,

The data may be scaled jointly or separately:

`1Mom` or `1MCD` for joint scaling of the classes,

`NMom` or `NMCD` for separate scaling of the classes.

You may use traditional moments or Minimum Covariance Determinant (MCD) estimates for mean and covariance:

`1Mom` or `NMom` for scaling using traditional data moments,

`1MCD` or `NMCD` for scaling using robust MCD data moments.

`kernel` `"EDKernel"` for the kernel of type 1/(1+kernel.bandwidth*EuclidianDistance2(x, y)),

`"GKernel"` [default and recommended] for the simple Gaussian kernel,

`"EKernel"` exponential kernel: exp(-kernel.bandwidth*EuclidianDistance(x, y)),

`"VarGKernel"` variable Gaussian kernel, where `kernel.bandwidth` is proportional to the `depth.zonoid` of a point.

`kernel.bandwidth` the bandwidth parameter of the kernel. If `NULL` - the Scott's rule of thumb is used. May be a single value for all classes, or a vector of values for each of the classes.

`mah.parMcd` is the value of the argument `alpha` for the function `covMcd`; is used when `pretransform = "*MCD"`.

Details

The potential representation is calculated in the same way as in `depth.potential`, see References below for more information and details.

Value

Matrix of objects, each object (row) is represented via its potentials (columns) w.r.t. each of the classes of the training sample; order of the classes in columns corresponds to the one in the argument `cardinalities`.

Examples

```
# Generate a bivariate normal location-shift classification task
# containing 20 training objects
class1 <- mvrnorm(50, c(0,0),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
class2 <- mvrnorm(50, c(1,1),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
data <- rbind(class1, class2)
plot(data, col = c(rep(1,50), rep(2,50)))
# potential with rule of thumb bandwidth
ds = depth.space.potential(data, c(50, 50))
# draw.ddplot(depth.space = ds, cardinalities = c(50, 50))

# potential with bandwidth = 0.5 and joint scaling
ds = depth.space.potential(data, c(50, 50), kernel.bandwidth = 0.5,
                           pretransform = "1Mom")
# draw.ddplot(depth.space = ds, cardinalities = c(50, 50))

# potential with bandwidth = 0.5 and separate scaling
ds = depth.space.potential(data, c(50, 50), kernel.bandwidth = 0.5,
                           pretransform = "NahMom") # or without pretransform
# draw.ddplot(depth.space = ds, cardinalities = c(50, 50))

data <- getdata("hemophilia")
cardinalities = c(sum(data$gr == "normal"), sum(data$gr == "carrier"))
ds = depth.space.potential(data[,1:2], cardinalities)
# draw.ddplot(depth.space = ds, cardinalities = cardinalities)
```

`depth.space.projection` *Calculate Depth Space using Projection Depth*

Description

Calculates the representation of the training classes in depth space using projection depth.

Usage

```
depth.space.projection(data, cardinalities,
                       method = "random", num.directions = 1000, seed = 0)
```

Arguments

`data`	Matrix containing training sample where each row is a d-dimensional object, and objects of each class are kept together so that the matrix can be thought of as containing blocks of objects representing classes.

`cardinalities` Numerical vector of cardinalities of each class in `data`, each entry corresponds to one class.

`method` to be used in calculations.

`"random"` Here the depth is determined as the minimum univariate depth of the data projected on lines in several directions. The directions are distributed uniformly on the $(d-1)$-sphere; the same direction set is used for all points.

`"linearize"` The Nelder-Mead method for function minimization, taken from Olsson, Journal of Quality Technology, 1974, 6, 56. R-codes of this function were written by Subhajit Dutta.

`num.directions` Number of random directions to be generated for `method = "random"`. With the growth of n the complexity grows linearly for the same number of directions.

`seed` the random seed. The default value `seed=0` makes no changes.

Details

The depth representation is calculated in the same way as in `depth.projection`, see 'References' for more information and details.

Value

Matrix of objects, each object (row) is represented via its depths (columns) w.r.t. each of the classes of the training sample; order of the classes in columns corresponds to the one in the argument `cardinalities`.

`depth.space.simplicial`

Calculate Depth Space using Simplicial Depth

Description

Calculates the representation of the training classes in depth space using simplicial depth.

Usage

```
depth.space.simplicial(data, cardinalities, exact = F, k = 0.05, seed = 0)
```

Arguments

`data`	Matrix containing training sample where each row is a d-dimensional object, and objects of each class are kept together so that the matrix can be thought of as containing blocks of objects representing classes.
`cardinalities`	Numerical vector of cardinalities of each class in `data`, each entry corresponds to one class.
`exact`	`exact=F` (by default) implies the approximative algorithm, considering `k` simplices, `exact=T` implies the exact algorithm.
`k`	Number ($k > 1$) or portion (if $0 < k < 1$) of simplices that are considered if `exact=F`. If $k > 1$, then the algorithmic complexity is polynomial in d but is independent of the number of observations in `data`, given k. If $0 < k < 1$, then the algorithmic complexity is exponential in the number of observations in `data`, but the calculation precision stays approximately the same.
`seed`	The random seed. The default value `seed=0` makes no changes.

Details

The depth representation is calculated in the same way as in `depth.simplicial`, see 'References' for more information and details.

Value

Matrix of objects, each object (row) is represented via its depths (columns) w.r.t. each of the classes of the training sample; order of the classes in columns corresponds to the one in the argument `cardinalities`.

depth.space.simplicialVolume

Calculate Depth Space using Simplicial Volume Depth

Description

Calculates the representation of the training classes in depth space using simplicial volume depth.

Usage

```
depth.space.simplicialVolume(data, cardinalities, exact = F, k = 0.05, seed = 0)
```

Arguments

`data`	Matrix containing training sample where each row is a d-dimensional object, and objects of each class are kept together so that the matrix can be thought of as containing blocks of objects representing classes.
`cardinalities`	Numerical vector of cardinalities of each class in `data`, each entry corresponds to one class.
`exact`	`exact=F` (by default) implies the approximative algorithm, considering `k` simplices, `exact=T` implies the exact algorithm.
`k`	Number ($k > 1$) or portion (if $0 < k < 1$) of simplices that are considered if `exact=F`. If $k > 1$, then the algorithmic complexity is polynomial in d but is independent of the number of observations in `data`, given k. If $0 < k < 1$, then the algorithmic complexity is exponential in the number of observations in `data`, but the calculation precision stays approximately the same.
`seed`	The random seed. The default value `seed=0` makes no changes.

Details

```

`depth.space.spatial` *Calculate Depth Space using Spatial Depth*

Description

Calculates the representation of the training classes in depth space using spatial depth.

Usage

```
depth.space.spatial(data, cardinalities, mah.estimate = "moment", mah.parMcd = 0.75)
```

Arguments

`data`	Matrix containing training sample where each row is a d-dimensional object, and objects of each class are kept together so that the matrix can be thought of as containing blocks of objects representing classes.
`cardinalities`	Numerical vector of cardinalities of each class in `data`, each entry corresponds to one class.
`mah.estimate`	is a character string specifying which estimates to use when calculating sample covariance matrix; can be `"none"`, `"moment"` or `"MCD"`, determining whether traditional moment or Minimum Covariance Determinant (MCD) (see `covMcd`) estimates for mean and covariance are used. By default `"moment"` is used. With `"none"` the non-affine invariant version of Spatial depth is calculated
`mah.parMcd`	is the value of the argument `alpha` for the function `covMcd`; is used when `mah.estimate = "MCD"`.

Details

The depth representation is calculated in the same way as in `depth.spatial`, see 'References' for more information and details.

Value

Matrix of objects, each object (row) is represented via its depths (columns) w.r.t. each of the classes of the training sample; order of the classes in columns corresponds to the one in the argument `cardinalities`.

---

depth.space.zonoid *Calculate Depth Space using Zonoid Depth*

Description

Calculates the representation of the training classes in depth space using zonoid depth.

Usage

```
depth.space.zonoid(data, cardinalities, seed = 0)
```

Arguments

`data`	Matrix containing training sample where each row is a d-dimensional object, and objects of each class are kept together so that the matrix can be thought of as containing blocks of objects representing classes.
`cardinalities`	Numerical vector of cardinalities of each class in `data`, each entry corresponds to one class.
`seed`	the random seed. The default value `seed=0` makes no changes.

Details

The depth representation is calculated in the same way as in `depth.zonoid`, see 'References' for more information and details.

Value

Matrix of objects, each object (row) is represented via its depths (columns) w.r.t. each of the classes of the training sample; order of the classes in columns corresponds to the one in the argument `cardinalities`.

Examples

```
# Generate a bivariate normal location-shift classification task
# containing 20 training objects
class1 <- mvrnorm(10, c(0,0),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
class2 <- mvrnorm(10, c(2,2),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
data <- rbind(class1, class2)
# Get depth space using zonoid depth
depth.space.zonoid(data, c(10, 10))

data <- getdata("hemophilia")
cardinalities = c(sum(data$gr == "normal"), sum(data$gr == "carrier"))
depth.space.zonoid(data[,1:2], cardinalities)
```

`depth.spatial` *Calculate Spatial Depth*

Description

Calculates the spatial depth of points w.r.t. a multivariate data set.

Usage

```
depth.spatial(x, data, mah.estimate = "moment", mah.parMcd = 0.75)
```

Arguments

`x`	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as `data`.
`data`	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.
`mah.estimate`	is a character string specifying which estimates to use when calculating sample covariance matrix; can be `"none"`, `"moment"` or `"MCD"`, determining whether traditional moment or Minimum Covariance Determinant (MCD) (see `covMcd`) estimates for mean and covariance are used. By default `"moment"` is used. With `"none"` the non-affine invariant version of Spatial depth is calculated
`mah.parMcd`	is the value of the argument `alpha` for the function `covMcd`; is used when `mah.estimate = "MCD"`.

Details

Calculates spatial depth. Spatial depth (also L1-depth) is a distance-based depth exploiting the idea of spatial quantiles of Chaudhuri (1996) and Koltchinskii (1997), formulated by Vardi & Zhang (2000) and Serfling (2002).

Value

Numerical vector of depths, one for each row in `x`; or one depth value if `x` is a numerical vector.

depth.zonoid *Calculate Zonoid Depth*

Description

Calculates the zonoid depth of points w.r.t. a multivariate data set.

Usage

```
depth.zonoid(x, data, seed = 0)
```

Arguments

x	Matrix of objects (numerical vector as one object) whose depth is to be calculated; each row contains a d-variate point. Should have the same dimension as data.
data	Matrix of data where each row contains a d-variate point, w.r.t. which the depth is to be calculated.
seed	the random seed. The default value seed=0 makes no changes.

Details

Calculates zonoid depth (Koshevoy and Mosler, 1997; Mosler, 2002) exactly based on the algorithm of Dyckerhoff, Koshevoy and Mosler (1996), implemented in C++ (and provided) by Rainer Dyckerhoff.

Value

Numerical vector of depths, one for each row in x; or one depth value if x is a numerical vector.

depthf. *Calculate Functional Depth*

Description

Calculates the depth of functions w.r.t. a functional data set.

The detailed descriptions are found in the corresponding topics.

Usage

```
depthf.(datafA, datafB, notion, ...)

## Adjusted band depth
# depthf.ABD(datafA, datafB, range = NULL, d = 101, norm = c("C", "L2"),
# J = 2, K = 1)

## Band depth
# depthf.BD(datafA, datafB, range = NULL, d = 101)

## Univariate integrated and infimal depth
# depthf.fd1(datafA, datafB, range = NULL, d = 101, order = 1, approx = 0)

## Bivariate integrated and infimal depth
# depthf.fd2(datafA, datafB, range = NULL, d = 101)

## h-mode depth
# depthf.hM(datafA, datafB, range = NULL, d = 101, norm = c("C", "L2"),
#  q = 0.2)

## Bivariate h-mode depth
# depthf.hM2(datafA, datafB, range = NULL, d = 101, q = 0.2)

## Half-region depth
# depthf.HR(datafA, datafB, range = NULL, d = 101)
```

```
## Univariate random projection depths
# depthf.RP1(datafA, datafB, range = NULL, d = 101, nproj = 50, nproj2 = 5)

# Bivariate random projection depths
# depthf.RP2(datafA, datafB, range = NULL, d = 101, nproj = 51)
```

Arguments

datafA	Functions whose depth is computed, represented by a dataf object of their arguments and functional values.
datafB	Random sample functions with respect to which the depth of datafA is computed. datafB is represented by a dataf object of their arguments and functional values.
notion	The name of the depth notion (shall also work with a user-defined depth function named "depthf.<name>").
...	Additional parameters passed to the depth functions.

Value

Numerical vector of depths, one for each function in datafA; or one depth value if datafA is a single function.

dataf2A = derivatives.est(datafA,deriv=c(0,1))
dataf2B = derivatives.est(datafB,deriv=c(0,1))

depthf.(dataf2A, dataf2B, notion = "fd2")
```

depthf.ABD *Adjusted Band Depth for Functional Data*

Description

The adjusted band depth of functional real-valued data based on either the C (uniform) norm, or on the L^2 norm of functions.

Usage

```
depthf.ABD(datafA, datafB, range = NULL, d = 101, norm = c("C", "L2"),
  J = 2, K = 1)
```

Arguments

datafA	Functions whose depth is computed, represented by a dataf object of their arguments and functional values. m stands for the number of functions.
datafB	Random sample functions with respect to which the depth of datafA is computed. datafB is represented by a dataf object of their arguments and functional values. n is the sample size. The grid of observation points for the functions datafA and datafB may not be the same.
range	The common range of the domain where the functions datafA and datafB are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in datafA and datafB.
d	Grid size to which all the functional data are transformed. For depth computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation, see Nagy et al. (2016).
norm	The norm used for the computation of the depth. Two possible choices are implemented: C for the uniform norm of continuous functions, and L2 for the L^2 norm of integrable functions.
J	The order of the adjusted band depth, that is the maximal number of functions taken in a band. Acceptable values are 2, 3,... By default this value is set to 2. Note that this is NOT the order as defined in the order-extended version of adjusted band depths in Nagy et al. (2016), used for the detection of shape outlying curves.
K	Number of sub-samples of the functions from B taken to speed up the computation. By default, sub-sampling is not performed. Values of K larger than 1 result in an approximation of the adjusted band depth.

Details

The function returns the vector of the sample adjusted band depth values. The kernel used in the evaluation is the function $K(u) = exp(-u)$.

Value

A vectors of length m of the adjusted band depths.

depthf.BD *Band Depth for Functional Data*

Description

The (unadjusted) band depth for functional real-valued data of order J=2.

Usage

```
depthf.BD(datafA, datafB, range = NULL, d = 101)
```

Arguments

datafA	Functions whose depth is computed, represented by a dataf object of their arguments and functional values. m stands for the number of functions.
datafB	Random sample functions with respect to which the depth of datafA is computed. datafB is represented by a dataf object of their arguments and functional values. n is the sample size. The grid of observation points for the functions datafA and datafB may not be the same.

range	The common range of the domain where the functions datafA and datafB are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in datafA and datafB.
d	Grid size to which all the functional data are transformed. For depth computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation.

Details

The function returns the vector of the sample (unadjusted) band depth values.

Value

A vector of length m of the band depth values.

depthf.fd1 *Univariate Integrated and Infimal Depth for Functional Data*

Description

Usual, and order extended integrated and infimal depths for real-valued functional data based on the halfspace and simplicial depth.

Usage

```
depthf.fd1(datafA, datafB, range = NULL, d = 101, order = 1, approx = 0)
```

Arguments

datafA	Functions whose depth is computed, represented by a dataf object of their arguments and functional values. m stands for the number of functions.
datafB	Random sample functions with respect to which the depth of datafA is computed. datafB is represented by a dataf object of their arguments and functional values. n is the sample size. The grid of observation points for the functions datafA and datafB may not be the same.
range	The common range of the domain where the functions datafA and datafB are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in datafA and datafB.
d	Grid size to which all the functional data are transformed. For depth computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation, see Nagy et al. (2016).
order	The order of the order extended integrated and infimal depths. By default, this is set to 1, meaning that the usual univariate depths of the functional values are computed. For order=2 or 3, the second and the third order extended integrated and infimal depths are computed, respectively.
approx	Number of approximations used in the computation of the order extended depth for order greater than 1. For order=2, the default value is set to 0, meaning that the depth is computed at all possible d^order combinations of the points in the domain. For order=3, the default value is set to 101. When approx is a positive integer, approx points are randomly sampled in [0,1]^order and at these points the order-variate depths of the corresponding functional values are computed.

Details

The function returns vectors of sample integrated and infimal depth values.

Value

Four vectors of length m of depth values are returned:

- Simpl_FD the integrated depth based on the simplicial depth,
- Half_FD the integrated depth based on the halfspace depth,
- Simpl_ID the infimal depth based on the simplicial depth,
- Half_ID the infimal depth based on the halfspace depth.

In addition, two vectors of length m of the relative area of smallest depth values is returned:

- Simpl_IA the proportions of points at which the depth Simpl_ID was attained,
- Half_IA the proportions of points at which the depth Half_ID was attained.

The values Simpl_IA and Half_IA are always in the interval [0,1]. They introduce ranking also among functions having the same infimal depth value - if two functions have the same infimal depth, the one with larger infimal area IA is said to be less central. For order=2 and m=1, two additional matrices of pointwise depths are also returned:

- PSD the matrix of size d*d containing the computed pointwise bivariate simplicial depths used for the computation of Simpl_FD and Simpl_ID,
- PHD the matrix of size d*d containing the computed pointwise bivariate halfspace depths used for the computation of Half_FD and Half_ID.

For order=3, only Half_FD and Half_ID are provided.

depthf.fd2 *Bivariate Integrated and Infimal Depth for Functional Data*

Description

Integrated and infimal depths of functional bivariate data (that is, data of the form $X : [a, b] \to R^2$, or $X : [a, b] \to R$ and the derivative of X) based on the bivariate halfspace and simplicial depths.

Usage

```
depthf.fd2(datafA, datafB, range = NULL, d = 101)
```

Arguments

datafA	Bivariate functions whose depth is computed, represented by a multivariate dataf object of their arguments (vector), and a matrix with two columns of the corresponding bivariate functional values. m stands for the number of functions.
datafB	Bivariate random sample functions with respect to which the depth of datafA is computed. datafB is represented by a multivariate dataf object of their arguments (vector), and a matrix with two columns of the corresponding bivariate functional values. n is the sample size. The grid of observation points for the functions datafA and datafB may not be the same.
range	The common range of the domain where the functions datafA and datafB are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in datafA and datafB.
d	Grid size to which all the functional data are transformed. For depth computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation.

Details

The function returns the vectors of sample integrated and infimal depth values.

Value

Four vectors of length m are returned:

- Simpl_FD the integrated depth based on the bivariate simplicial depth,
- Half_FD the integrated depth based on the bivariate halfspace depth,
- Simpl_ID the infimal depth based on the bivariate simplicial depth,
- Half_ID the infimal depth based on the bivariate halfspace depth.

In addition, two vectors of length m of the relative area of smallest depth values is returned:

- Simpl_IA the proportions of points at which the depth Simpl_ID was attained,
- Half_IA the proportions of points at which the depth Half_ID was attained.

The values Simpl_IA and Half_IA are always in the interval [0,1]. They introduce ranking also among functions having the same infimal depth value - if two functions have the same infimal depth, the one with larger infimal area IA is said to be less central.

depthf.hM *h-Mode Depth for Functional Data*

Description

The h-mode depth of functional real-valued data.

Usage

```
depthf.hM(datafA, datafB, range = NULL, d = 101, norm = c("C", "L2"),
  q = 0.2)
```

Arguments

datafA	Functions whose depth is computed, represented by a dataf object of their arguments and functional values. m stands for the number of functions.
datafB	Random sample functions with respect to which the depth of datafA is computed. datafB is represented by a dataf object of their arguments and functional values. n is the sample size. The grid of observation points for the functions datafA and datafB may not be the same.
range	The common range of the domain where the functions datafA and datafB are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in datafA and datafB.
d	Grid size to which all the functional data are transformed. For depth computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation.

norm	The norm used for the computation of the depth. Two possible choices are implemented: C for the uniform norm of continuous functions, and L2 for the L^2 norm of integrable functions.
q	The quantile used to determine the value of the bandwidth h in the computation of the h-mode depth. h is taken as the q-quantile of all non-zero distances between the functions B. By default, this value is set to q=0.2, in accordance with the choice of Cuevas et al. (2007).

Details

The function returns the vectors of the sample h-mode depth values. The kernel used in the evaluation is the standard Gaussian kernel, the bandwidth value is chosen as a quantile of the non-zero distances between the random sample curves.

Value

A vector of length m of the h-mode depth values.

```

---

depthf.hM2 *Bivariate h-Mode Depth for Functional Data Based on the L^2 Metric*

Description

The h-mode depth of functional bivariate data (that is, data of the form $X : [a, b] \to R^2$, or $X : [a, b] \to R$ and the derivative of X) based on the L^2 metric of functions.

Usage

```
depthf.hM2(datafA, datafB, range = NULL, d = 101, q = 0.2)
```

Arguments

datafA	Bivariate functions whose depth is computed, represented by a multivariate dataf object of their arguments (vector), and a matrix with two columns of the corresponding bivariate functional values. m stands for the number of functions.
datafB	Bivariate random sample functions with respect to which the depth of datafA is computed. datafB is represented by a multivariate dataf object of their arguments (vector), and a matrix with two columns of the corresponding bivariate functional values. n is the sample size. The grid of observation points for the functions datafA and datafB may not be the same.
range	The common range of the domain where the functions datafA and datafB are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in datafA and datafB.
d	Grid size to which all the functional data are transformed. For depth computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation.
q	The quantile used to determine the value of the bandwidth h in the computation of the h-mode depth. h is taken as the q-quantile of all non-zero distances between the functions B. By default, this value is set to q=0.2, in accordance with the choice of Cuevas et al. (2007).

Details

The function returns the vectors of sample h-mode depth values. The kernel used in the evaluation is the standard Gaussian kernel, the bandwidth value is chosen as a quantile of the non-zero distances between the random sample curves.

Value

Three vectors of length m of h-mode depth values are returned:

- hM the unscaled h-mode depth,
- hM_norm the h-mode depth hM linearly transformed so that its range is [0,1],
- hM_norm2 the h-mode depth FD linearly transformed by a transformation such that the range of the h-mode depth of B with respect to B is [0,1]. This depth may give negative values.

depthf.HR *Half-Region Depth for Functional Data*

Description

The half-region depth for functional real-valued data.

Usage

```
depthf.HR(datafA, datafB, range = NULL, d = 101)
```

Arguments

datafA	Functions whose depth is computed, represented by a dataf object of their arguments and functional values. m stands for the number of functions.
datafB	Random sample functions with respect to which the depth of datafA is computed. datafB is represented by a dataf object of their arguments and functional values. n is the sample size. The grid of observation points for the functions datafA and datafB may not be the same.
range	The common range of the domain where the functions datafA and datafB are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in datafA and datafB.
d	Grid size to which all the functional data are transformed. For depth computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation.

Details

The function returns the vector of the sample half-region depth values.

Value

A vector of length m of the half-region depth values.

depthf.RP1 *Univariate Random Projection Depths for Functional Data*

Description

Random projection depth and random functional depth for functional data.

Usage

```
depthf.RP1(datafA, datafB, range = NULL, d = 101, nproj = 50, nproj2 = 5)
```

Arguments

datafA	Functions whose depth is computed, represented by a dataf object of their arguments and functional values. m stands for the number of functions.
datafB	Random sample functions with respect to which the depth of datafA is computed. datafB is represented by a dataf object of their arguments and functional values. n is the sample size. The grid of observation points for the functions datafA and datafB may not be the same.
range	The common range of the domain where the functions datafA and datafB are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in datafA and datafB.

d	Grid size to which all the functional data are transformed. For depth computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation.
nproj	Number of projections taken in the computation of the random projection depth. By default taken to be 51.
nproj2	Number of projections taken in the computation of the random functional depth. By default taken to be 5. nproj2 should be much smaller than d, the dimensionality of the discretized functional data.

Details

The function returns the vectors of sample random projection, and random functional depth values. The random projection depth described in Cuevas et al. (2007) is based on the average univariate depth of one-dimensional projections of functional data. The projections are taken randomly as a sample of standard normal d-dimensional random variables, where d stands for the dimensionality of the discretized functional data.

The random functional depth (also called random Tukey depth, or random halfspace depth) is described in Cuesta-Albertos and Nieto-Reyes (2008). The functional data are projected into the real line in random directions as for the random projection depths. Afterwards, an approximation of the halfspace (Tukey) depth based on this limited number of univariate projections is assessed.

Value

Three vectors of depth values of length m are returned:

- Simpl_FD the random projection depth based on the univariate simplicial depth,
- Half_FD the random projection depth based on the univariate halfspace depth,
- RHalf_FD the random halfspace depth.

depthf.RP2 *Bivariate Random Projection Depths for Functional Data*

Description

Double random projection depths of functional bivariate data (that is, data of the form $X : [a, b] \to R^2$, or $X : [a, b] \to R$ and the derivative of X).

Usage

```
depthf.RP2(datafA, datafB, range = NULL, d = 101, nproj = 51)
```

Arguments

datafA	Bivariate functions whose depth is computed, represented by a multivariate dataf object of their arguments (vector), and a matrix with two columns of the corresponding bivariate functional values. m stands for the number of functions.
datafB	Bivariate random sample functions with respect to which the depth of datafA is computed. datafB is represented by a multivariate dataf object of their arguments (vector), and a matrix with two columns of the corresponding bivariate functional values. n is the sample size. The grid of observation points for the functions datafA and datafB may not be the same.
range	The common range of the domain where the functions datafA and datafB are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in datafA and datafB.
d	Grid size to which all the functional data are transformed. For depth computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation.
nproj	Number of projections taken in the computation of the double random projection depth. By default taken to be 51.

Details

The function returns the vectors of sample double random projection depth values. The double random projection depths are described in Cuevas et al. (2007). They are of two types: RP2 type, and RPD type. Both types of depths are based on bivariate projections of the bivariate functional data. These projections are taken randomly as a sample of standard normal d-dimensional random

variables, where d stands for the dimensionality of the internally represented discretized functional data. For RP2 type depths, the average bivariate depth of the projected quantities is assessed. For RPD type depths, further univariate projections of these bivariate projected quantities are evaluated, and based on these final univariate quantities, the average univariate depth is computed.

Value

Five vectors of length m are returned:

- Simpl_FD the double random projection depth RP2 based on the bivariate simplicial depth,
- Half_FD the double random projection depth RP2 based on the bivariate halfspace depth,
- hM_FD the double random projection depth RP2 based on the bivariate h-mode depth,
- Simpl_DD the double random projection depth RPD based on the univariate simplicial depth,
- Half_DD the random projection depth RPD based on the univariate halfspace depth,

```

---

derivatives.est *Estimation of the First Two Derivatives for Functional Data*

Description

Returns the estimated values of derivatives of functional data.

Usage

```
derivatives.est(dataf, range = NULL, d = 101, spar = NULL, deriv = c(0,
  1))
```

Arguments

dataf	Functional dataset, represented by a dataf object of their arguments and functional values. m stands for the number of functions.
range	The common range of the domain where the functions dataf are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in dataf.
d	Grid size to which all the functional data are transformed. For computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation.
spar	If provided, this parameter is passed to functions D1ss and D2ss from package sfsmisc as the value of the smoothing spline parameter in order to numerically approximate the derivatives of dataf.
deriv	A vector composed of 0, 1, and 2 of the demanded functional values / derivatives of the functions in the rows of dataf. 0 stands for the functional values, 1 for the first derivatives, 2 for the second derivatives.

Details

If the input dataf is a functional random sample of size m, the function returns a dataf object of nd-dimensional functional data, where in the elements of the vector-valued functional data represent the estimated values of the derivatives of dataf. All derivatives are evaluated at an equi-distant grid of d points in the domain given by range. nd here stands for 1, 2 or 3, depending on how many derivatives of dataf are requested to be computed. For the estimation, functions D1ss and D2ss from the package sfsmisc are utilized.

Value

A multivariate dataf object of the functional values and / or the derivatives of dataf. The dimensionality of the vector-valued functional data is nd. The arguments of the data are all equal to an equi-distant grid of d points in the domain given by range. nd is the demanded number of derivatives at the output, i.e. the length of the vector deriv.

`dknn.classify` *Depth-Based kNN*

Description

The implementation of the affine-invariant depth-based kNN of Paindaveine and Van Bever (2015).

Usage

```
dknn.classify(objects, data, k, depth = "halfspace", seed = 0)
```

Arguments

`objects`	Matrix containing objects to be classified; each row is one d-dimensional object.
`data`	Matrix containing training sample where each of n rows is one object of the training sample where first d entries are inputs and the last entry is output (class label).
`k`	the number of neighbours
`depth`	Character string determining which depth notion to use; the default value is `"halfspace"`. Currently the method supports the following depths: "halfspace", "Mahalanobis", "simplicial".
`seed`	the random seed. The default value `seed=0` makes no changes.

Value

List containing class labels, or character string "Ignored" for the outsiders if "Ignore" was specified as the outsider treating method.

References

Paindaveine, D. and Van Bever, G. (2015). Nonparametrically consistent depth-based classifiers. *Bernoulli* **21** 62–82.

See Also

`dknn.train` to train the Dknn-classifier.

`dknn.classify.trained` to classify with the Dknn-classifier.

`ddalpha.train` to train the DDα-classifier.

`ddalpha.getErrorRateCV` and `ddalpha.getErrorRatePart` to get error rate of the Dknn-classifier on particular data (set `separator = "Dknn"`).

Examples

```
# Generate a bivariate normal location-shift classification task
# containing 200 training objects and 200 to test with
class1 <- mvrnorm(200, c(0,0),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
class2 <- mvrnorm(200, c(2,2),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
trainIndices <- c(1:100)
testIndices <- c(101:200)
propertyVars <- c(1:2)
classVar <- 3
trainData <- rbind(cbind(class1[trainIndices,], rep(1, 100)),
                   cbind(class2[trainIndices,], rep(2, 100)))
testData <- rbind(cbind(class1[testIndices,], rep(1, 100)),
                  cbind(class2[testIndices,], rep(2, 100)))
data <- list(train = trainData, test = testData)

# Train the classifier
# and get the classification error rate
cls <- dknn.train(data$train, kMax = 20, depth = "Mahalanobis")
cls$k
classes1 <- dknn.classify.trained(data$test[,propertyVars], cls)
cat("Classification error rate: ",
    sum(unlist(classes1) != data$test[,classVar])/200)

# Classify the new data based on the old ones in one step
classes2 <- dknn.classify(data$test[,propertyVars], data$train, k = cls$k, depth = "Mahalanobis")
cat("Classification error rate: ",
    sum(unlist(classes2) != data$test[,classVar])/200)
```

`dknn.classify.trained` *Depth-Based kNN*

Description

The implementation of the affine-invariant depth-based kNN of Paindaveine and Van Bever (2015).

Usage

```
dknn.classify.trained(objects, dknn)
```

Arguments

`objects`	Matrix containing objects to be classified; each row is one d-dimensional object.
`dknn`	Dknn-classifier (obtained by `dknn.train`).

Value

List containing class labels, or character string "Ignored" for the outsiders if "Ignore" was specified as the outsider treating method.

References

Paindaveine, D. and Van Bever, G. (2015). Nonparametrically consistent depth-based classifiers. *Bernoulli* **21** 62–82.

cls$k
classes1 <- dknn.classify.trained(data$test[,propertyVars], cls)
cat("Classification error rate: ",
    sum(unlist(classes1) != data$test[,classVar])/200)

# Classify the new data based on the old ones in one step
classes2 <- dknn.classify(data$test[,propertyVars], data$train, k = cls$k, depth = "Mahalanobis")
cat("Classification error rate: ",
    sum(unlist(classes2) != data$test[,classVar])/200)
```

dknn.train *Depth-Based kNN*

Description

The implementation of the affine-invariant depht-based kNN of Paindaveine and Van Bever (2015).

Usage

```
dknn.train(data, kMax = -1, depth = "halfspace", seed = 0)
```

Arguments

data	Matrix containing training sample where each of n rows is one object of the training sample where first d entries are inputs and the last entry is output (class label).
kMax	the maximal value for the number of neighbours. If the value is set to -1, the default value is calculated as n/2, but at least 2, at most n-1.
depth	Character string determining which depth notion to use; the default value is "halfspace". Currently the method supports the following depths: "halfspace", "Mahalanobis", "simplicial".
seed	the random seed. The default value seed=0 makes no changes.

Value

The returned object contains technical information for classification, including the found optimal value k.

```

---

draw.ddplot *Draw* DD-*Plot*

Description

The function draws the *DD*-plot either of the existing DDα-classifier of the depth space. Also accessible from `plot.ddalpha`.

Usage

```
draw.ddplot(ddalpha, depth.space, cardinalities,
            main = "DD plot", xlab = "C1", ylab = "C2", xlim, ylim,
            classes = c(1, 2), colors = c("red", "blue", "green"), drawsep = T)
```

Arguments

`ddalpha`	DDα-classifier (obtained by `ddalpha.train`).
`depth.space`	The ready depth space obtained by `depth.space.`
`cardinalities`	Numerical vector of cardinalities of each class in `data`, each entry corresponds to one class.
`main`	an overall title for the plot: see `title`
`xlab, ylab`	class labels
`xlim, ylim`	range of axis
`classes`	vector of numbers of two classes used for depth calculation
`colors`	vector of the classes' colors
`drawsep`	draws the separation on the DD-plot (currently for 2 classes and not for knn)

See Also

`ddalpha.train`

`depth.space.`

Examples

```
data = getdata("kidney")

#1. using the existing ddalpha classifier
ddalpha = ddalpha.train(data, depth = "spatial")
draw.ddplot(ddalpha, main = "DD-plot")

#2. using depth.space.
# Sort the data w.r.t. classes
data = rbind(data[data$C == 1,], data[data$C == 2,])
cardinalities = c(sum(data$C == 1), sum(data$C == 2))

dspace = depth.space.spatial(data[,-6], cardinalities = cardinalities)
draw.ddplot(depth.space = dspace, cardinalities = cardinalities,
            main = "DD-plot", xlab = 1, ylab = 2)
```

FKS *Fast Kernel Smoothing*

Description

Produces a kernel smoothed version of a function based on the vectors given in the input. Bandwidth is selected using cross-validation.

Usage

```
FKS(dataf, Tout, kernel = c("uniform", "triangular", "Epanechnikov",
  "biweight", "triweight", "Gaussian"), m = 51, K = 20)
```

Arguments

dataf	A set of functional data given by a dataf object that are to be smoothed.
Tout	vector of values in the domain of the functions at which the resulting smoothed function is evaluated
kernel	Kernel used for smoothing. Admissible values are uniform, triangular, Epanechnikov, biweight, triweight and Gaussian. By default, uniform is used.
m	Number of points in the grid for choosing the cross-validated bandwidth.
K	Performs K-fold cross-validation based on randomly shuffled data.

Details

A vector of the same length as Tout corresponding to the values of the function produced using kernel smoothing, is provided. Bandwidth is selected using the K-fold cross-validation of randomly shuffled input values.

Value

A dataf object corresponding to Tout of smoothed functional values.

Author(s)

Stanislav Nagy, <nagy at karlin.mff.cuni.cz>

Examples

```
d = 10
T = sort(runif(d))
X = T^2+ rnorm(d,sd=.1)
Tout = seq(0,1,length=101)

plot(T,X)
dataf = list(list(args=T,vals=X))
data.sm = FKS(dataf,Tout,kernel="Epan")
lines(data.sm[[1]]$args,data.sm[[1]]$vals,col=2)

datafs = structure(list(dataf=dataf,labels=1:length(dataf)),class="functional")
plot(datafs)
points(T,X)
data.sms = structure(list(dataf=data.sm,labels=1:length(data.sm)),class="functional")
plot(data.sms)

n = 6
dataf = list()
for(i in 1:n) dataf[[i]] = list(args = T<-sort(runif(d)), vals = T^2 + rnorm(d,sd=.1))
data.sm = FKS(dataf,Tout,kernel="triweight")
data.sms = structure(list(dataf=data.sm,labels=1:length(data.sm)),class="functional")
plot(data.sms)
```

getdata *Data for Classification*

Description

50 multivariate data sets for binary classification. For more details refer http://www.wisostat.uni-koeln.de/de/forschung/software-und-daten/data-for-classification/

The getdata function gets the data set from the package, and returns it. The dataset itself does not appear in the global environment and the existing variables with the same name remain unchanged.

Usage

```
# load the data set
# data(name)

# load the data set by name
# data(list = "name")

# load the data set by name to a variable
# getdata("name")
```

Arguments

name	the data set name.

Format

A data frame with n observations on the d variables. The last d+1 column is the class label.

x[,1:d] numeric values

x[,d+1] the numeric class label (0 or 1) or (1 or 2)

Details

The package contains data sets used in the joint project of the University of Cologne and the Hochschule Merseburg "Classifying real-world data with the DDalpha-procedure". Comprehensive description of the methodology, and experimental settings and results of the study are presented in the work:

Mozharovskyi, P., Mosler, K., and Lange, T. (2015). Classifying real-world data with the DDα-procedure. *Advances in Data Analysis and Classification* **9** 287–314.

For a more complete explanation of the technique and further experiments see: Lange, T., Mosler, K., and Mozharovskyi, P. (2014). Fast nonparametric classification based on data depth. *Statistical Papers* **55** 49–69.

50 binary classification tasks have been obtained from partitioning 33 freely accessible data sets. Multiclass problems were reasonably split into binary classification problems, some of the data set

were slightly processed by removing objects or attributes and selecting prevailing classes. Each data set is provided with a (short) description and brief descriptive statistics. The name reflects the origination of the data. A letter after the name is a property filter, letters (also their combinations) in brackets separated by "vs" are the classes opposed. The letters (combinations or words) stand for labels of classes (names of properties) and are intuitive. Each description contains a link to the original data.

The data have been collected as open source data in January 2013. Owners of the package decline any responsibility regarding their correctness or consequences of their usage. If you publish material based on these data, please quote the original source. Special requests regarding citations are found on data set's web page.

infimalRank *Adjusted Ranking of Functional Data Based on the Infimal Depth*

Description

Returns a vector of adjusted depth-based ranks for infimal depth for functional data.

Usage

```
infimalRank(ID, IA, ties.method = "max")
```

Arguments

ID	The vector of infimal depths of the curves of length n.
IA	The vector of the infimal areas corresponding to the infimal depths from ID of length n.
ties.method	Parameter for breaking ties in infimal area index. By default max, see rank.

Details

Infimal depths for functional data tend to give to many functional observations the same value of depth. Using this function, the data whose depth is the same is ranked according to the infimal area indicator. This indicator is provided in functions depthf.fd1 along the value of the infimal depth.

Value

A vector of length n. Low depth values mean high ranks, i.e. potential outlyingness. If some of the infimal depths are identical, the ranking of these functions is made according to the values of the infimal area. There, higher infimal area index means higher rank, i.e. non-centrality.

Author(s)

Stanislav Nagy, <nagy at karlin.mff.cuni.cz>

References

Nagy, S., Gijbels, I. and Hlubinka, D. (2017). Depth-based recognition of shape outlying functions. *Journal of Computational and Graphical Statistics*, **26** (4), 883–893.

Examples

```
datafA = dataf.population()$dataf[1:20]
datafB = dataf.population()$dataf[21:50]
D = depthf.fd1(datafA,datafB)
infimalRank(D$Half_ID,D$Half_IA)

ID = c(0,1,0,0,0,1,1)
IA = c(2,3,1,0,2,4,1)
infimalRank(ID,IA)
```

---

is.in.convex *Check Outsiderness*

Description

Checks the belonging to at least one of class convex hulls of the training sample.

Usage

```
is.in.convex(x, data, cardinalities, seed = 0)
```

Arguments

x	Matrix of objects (numerical vector as one object) whose belonging to convex hulls is to be checked; each row contains a d-variate point. Should have the same dimension as data.
data	Matrix containing training sample where each row is a d-dimensional object, and objects of each class are kept together so that the matrix can be thought of as containing blocks of objects, representing classes.
cardinalities	Numerical vector of cardinalities of each class in data, each entry corresponds to one class.
seed	the random seed. The default value seed=0 makes no changes.

Details

Checks are conducted w.r.t. each separate class in data using the simplex algorithm, taken from the C++ implementation of the zonoid depth calculation by Rainer Dyckerhoff.

Value

Matrix of number of objects rows and number of classes columns, containing 1 if an object belongs to the convex hull of the corresponding class, and 0 otherwise.

Author(s)

Implementation of the simplex algorithm is taken from the algorithm for computation of zonoid depth (Dyckerhoff, Koshevoy and Mosler, 1996) that has been implemented in C++ by Rainer Dyckerhoff.

References

Dyckerhoff, R., Koshevoy, G., and Mosler, K. (1996). Zonoid data depth: theory and computation. In: Prat A. (ed), *COMPSTAT 1996. Proceedings in computational statistics*, Physica-Verlag (Heidelberg), 235–240.

Examples

```
# Generate a bivariate normal location-shift classification task
# containing 400 training objects and 1000 to test with
class1 <- mvrnorm(700, c(0,0),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
class2 <- mvrnorm(700, c(2,2),
                  matrix(c(1,1,1,4), nrow = 2, ncol = 2, byrow = TRUE))
trainIndices <- c(1:200)
testIndices <- c(201:700)
propertyVars <- c(1:2)
classVar <- 3
trainData <- rbind(cbind(class1[trainIndices,], rep(1, 200)),
                   cbind(class2[trainIndices,], rep(2, 200)))
testData <- rbind(cbind(class1[testIndices,], rep(1, 500)),
                  cbind(class2[testIndices,], rep(2, 500)))
data <- list(train = trainData, test = testData)

# Count outsiders
numOutsiders = sum(rowSums(is.in.convex(data$test[,propertyVars],
                                data$train[,propertyVars], c(200, 200))) == 0)
cat(numOutsiders, "outsiders found in the testing sample.\n")
```

`L2metric` *Fast Computation of the L^2 Metric for Sets of Functional Data*

Description

Returns the matrix of L^2 distances between two sets of functional data.

Usage

```
L2metric(A, B)
```

Arguments

`A`	Functions of the first set, represented by a matrix of their functional values of size `m*d`. `m` stands for the number of functions, `d` is the number of the equi-distant points 1,...,d in the domain of the data [1,d] at which the functional values of the `m` functions are evaluated.

B — Functions of the second set, represented by a matrix of their functional values of size n*d. n stands for the number of functions, d is the number of the equidistant points 1,...,d in the domain of the data [1,d] at which the functional values of the n functions are evaluated. The grid of observation points for the functions A and B must be the same.

Details

For two sets of functional data of sizes m and n represented by matrices of their functional values on the common domain 1,...,d, this function returns the symmetric matrix of size m*n whose entry in the i-th row and j-th column is the approximated L^2 distance of the i-th function from the first set, and the j-th function from the second set. This function is utilized in the computation of the h-mode depth.

Value

A symmetric matrix of the distances of the functions of size m*n.

plot.ddalpha *Plots for the "ddalpha" Class*

Description

depth.contours.ddalpha – builds the data depth contours for multiclass 2-dimensional data using the trained classifier. draw.ddplot – draws the *DD*-plot of the existing DDα-classifier.

Usage

```
## S3 method for class 'ddalpha'
plot(x, type = c("ddplot", "depth.contours"), ...)
```

Arguments

x	DDα-classifier (obtained by ddalpha.train).
type	type of the plot for draw.ddplot or depth.contours.ddalpha
...	additional parameters passed to the depth functions and to plot

See Also

depth.

depth.contours

depth.graph

Examples

```
## Not run:

par(mfrow = c(2,2))
data(hemophilia)

ddalpha = ddalpha.train(hemophilia, depth = "none")
plot(ddalpha, type = "depth.contours", main = "data")
plot(ddalpha, type = "ddplot", main = "data", drawsep = F)

for (depth in c("zonoid", "Mahalanobis", "projection", "spatial")){
  ddalpha = ddalpha.train(hemophilia, depth = depth)
  plot(ddalpha, type = "depth.contours", main = depth, drawsep = T)
  plot(ddalpha, type = "ddplot", main = depth)
}

## End(Not run)
```

---

plot.ddalphaf *Plots for the "ddalphaf" Class*

Description

plot.functional – plots the functional data used by classifier

depth.contours.ddalpha – builds the data depth contours for multiclass 2-dimensional data using the trained classifier. draw.ddplot – draws the *DD*-plot of the existing DDα-classifier.

Usage

```
## S3 method for class 'ddalphaf'
plot(x, type = c("functional.data", "ddplot", "depth.contours"), ...)
```

Arguments

x	functional DDα-classifier (obtained by ddalphaf.train).
type	type of the plot for plot.functional, draw.ddplot or depth.contours.ddalpha
...	additional parameters passed to the depth functions and to plot

See Also

depth.

depth.contours

depth.graph

Examples

```
## Not run:

dataf = dataf.growth()
ddalphaf = ddalphaf.train (dataf$dataf, dataf$labels,
                           classifier.type = "ddalpha", maxNumIntervals = 2)

# plot the functional data
plot(ddalphaf)

# plot depth contours and separation in the transformed space
# (possible only if maxNumIntervals = 2)
plot(ddalphaf, type = "depth.contours")

# plot the DD-plot
plot(ddalphaf, type = "ddplot")

## End(Not run)
```

---

plot.functional *Plot functions for the Functional Data*

Description

Plots the functional data given in the form which is described in the topic dataf.*.

Usage

```
## S3 method for class 'functional'
plot(x,
      main = "Functional data", xlab = "args", ylab = "vals",
      colors = c("red", "blue", "green", "black", "orange", "pink"), ...)
```

```
## S3 method for class 'functional'
lines(x,
      colors = c("red", "blue", "green", "black", "orange", "pink"), ...)

## S3 method for class 'functional'
points(x,
      colors = c("red", "blue", "green", "black", "orange", "pink"), ...)
```

Arguments

x	The functional data as in the topic dataf.*. Note, that the in order to use s3 methods the data must be of class "functional".
main	an overall title for the plot: see title
xlab	a title for the x axis: see title
ylab	a title for the y axis: see title
colors	the colors for the classes of the data. The colors are applied to the classes sorted in alphabetical order. Use the same set of classes to ensure that the same colours are selected in lines and points as in plot (do not remove entire classes).
...	additional parameters

See Also

dataf.* for functional data description

Examples

```
## Not run:
  ## load the Growth dataset
  dataf = dataf.growth()

  labels = unlist(dataf$labels)
  plot(dataf,
       main = paste("Growth: girls red (", sum(labels == "girl"), "),",
                    " boys blue (", sum(labels == "boy"), ")", sep=""),
       xlab="Year", ylab="Height, cm",
       colors = c("blue", "red")   # in alphabetical order of class labels
  )

  # plot an observation as a line
  observation = structure(list(dataf = list(dataf$dataf[[1]])), class = "functional")
  lines(observation, colors = "green", lwd = 3)

  # plot hight at the age of 14
  indexAge14 = which(observation$dataf[[1]]$args == 14)
  hightAge14 = observation$dataf[[1]]$vals[indexAge14]
  atAge14 = structure(list(
                      dataf = list(dataf = list(args = 14, vals = hightAge14))
                      ), class = "functional")
  points(atAge14, colors = "yellow", pch = 18)
```

```
## End(Not run)
```

---

rawfd2dataf *Transform Raw Functional Data to a* dataf *Object*

Description

Constructs a (possibly multivariate) functional data object given by an array of its functional values evaluated at an equi-distant grid of points, and transforms it into a dataf object more suitable for work in the ddalpha package.

Usage

```
rawfd2dataf(X, range)
```

Arguments

X	Either a matrix of size n*d, or an array of dimension n*d*k of functional values. Here n stands for the number of functions, d is the number of equi-distant points in the domain where the functional values are evaluated, and if applicable, k is the dimensionality of the (vector-valued) functional data.
range	A vector of size two that represents the endpoints of the common domain of all functions X.

Value

A (possibly multivariate) dataf object corresponding to the functional data X evaluated at an equi-distant grid of points.

Author(s)

Stanislav Nagy, <nagy at karlin.mff.cuni.cz>

```
## transform a matrix into a functional data set
n = 5
d = 21
X = matrix(rnorm(n*d),ncol=d)
rawfd2dataf(X,range=c(0,1))

## transform an array into a multivariate functional data set
k = 3
X = array(rnorm(n*d*k),dim=c(n,d,k))
rawfd2dataf(X,range=c(-1,1))
```

---

resetPar *Reset Graphical Parameters*

Description

The function returns the default graphical parameters for par.

Usage

```
resetPar()
```

Details

The returned parameters are used as input parameters for par.

Value

The list of graphical parameters described in the 'Graphical Parameters' section of par.

Examples

```
par(mfrow = c(1,2), mar = c(2,2,2,2))
plot(sin, -pi, 2*pi)
plot(cos, -pi, 2*pi)

par(resetPar())
plot(sin, -pi, 2*pi)
plot(cos, -pi, 2*pi)
```

shape.fd.analysis *Diagnostic Plot for First and Second Order Integrated and Infimal Depths*

Description

Produce the diagnostic plot based on the fist or second order extended integrated / infimal depths.

Usage

```
shape.fd.analysis(datafA, datafB, range = NULL, d = 101, order = 1,
  method = c("halfspace", "simplicial"), approx = 0, title = "",
  nfun = 10, plot = TRUE)
```

Arguments

datafA	A single function whose depth is computed, represented by a dataf object of arguments and functional values.
datafB	Functional dataset with respect to which the depth of datafA is computed. datafB is represented by a dataf object of arguments and functional values. n stands for the number of functions. The grid of observation points for the functions in datafA and datafB may not be the same.
range	The common range of the domain where the functions datafA and datafB are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in datafA and datafB.
d	Grid size to which all the functional data are transformed. For depth computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation.
order	The order of the depth to be used in the plot, for order=1 produces the plot of univariate marginal depth of A and nfun functions from B over the domain of the functions. For order=2 produces the bivariate contour plot of the bivariate depths of A at couples of points from the domain.
method	The depth that is used in the diagnostic plot. possible values are halfspace for the halfspace depth, or simplicial for the simplicial depth.
approx	For order=2, the number of approximations used in the computation of the order extended depth. By default this is set to 0, meaning that the depth is computed at all possible d^2 combinations of the points in the domain. When set to a positive integer, approx bivariate points are randomly sampled in unit square, and at these points the bivariate depths of the corresponding functional values are computed.
title	The title of the diagnostic plot.

nfun	For order=1, the number of functions from B whose coordinate-wise univariate depths of functional values should be displayed with the depth of A. The depth of A is displayed in solid red line, the depths of the functions from B in dashed black.
plot	Logical: should the function by plotted?

Details

Plots a diagnostic plot of pointwise univariate (or bivariate) depths for all possible points (or couples of points) from the domain of the functional data. From such a plot it is possible to infer into the first order (or second order) properties of a single function x with respect to the given set of functional data. For order=1, the integral of the displayed function is the integrated depth of x, the smallest value of the function is the infimal depth of x. For order=2, the bivariate integral of the displayed surface gives the second order extended integrated depth of x, the infimum of this bivariate function gives the second order infimal depth of x. For details see Nagy et al. (2016) and depthf.fd1.

Value

For order=1 two depth values, and two vectors of pointwise depths:

- Simpl_FD the first order integrated depth based on the simplicial depth,
- Half_FD the first order integrated depth based on the halfspace depth,
- Simpl_ID the first order infimal depth based on the simplicial depth,
- Half_ID the first order infimal depth based on the halfspace depth,
- PSD the vector of length d containing the computed pointwise univariate simplicial depths used for the computation of Simpl_FD and Simpl_ID,
- PHD the vector of length d containing the computed pointwise univariate halfspace depths used for the computation of Half_FD and Half_ID.

In addition, the first order integrated / infimal depth diagnostic plot of the function A with respect to the random sample given by the functions corresponding to the rows of the matrix B is produced.

For order=2 four depth values, and two matrices of pointwise depths:

- Simpl_FD the second order integrated depth based on the simplicial depth,
- Half_FD the second order integrated depth based on the halfspace depth,
- Simpl_ID the second order infimal depth based on the simplicial depth,
- Half_ID the second order infimal depth based on the halfspace depth,
- PSD the matrix of size d*d containing the computed pointwise bivariate simplicial depths used for the computation of Simpl_FD and Simpl_ID,
- PHD the matrix of size d*d containing the computed pointwise bivariate halfspace depths used for the computation of Half_FD and Half_ID.

In addition, the second order integrated / infimal depth diagnostic plot of the function A with respect to the random sample given by the functions corresponding to the rows of the matrix B is produced.

shape.fd.analysis(datafA,dataf,order=2,approx=0)
```

---

shape.fd.outliers *Functional Depth-Based Shape Outlier Detection*

Description

Detects functional outliers of first three orders, based on the order extended integrated depth for functional data.

Usage

```
shape.fd.outliers(dataf, range = NULL, d = 101, q = 0.05,
  method = c("halfspace", "simplicial"), approx = 100, print = FALSE,
  plotpairs = FALSE, max.order = 3, exclude.out = TRUE,
  output = c("matrix", "list"), identifiers = NULL)
```

Arguments

dataf	Functional dataset, represented by a dataf object of their arguments and functional values. n stands for the number of functions.
range	The common range of the domain where the fucntions dataf are observed. Vector of length 2 with the left and the right end of the interval. Must contain all arguments given in dataf.
d	Grid size to which all the functional data are transformed. For depth computation, all functional observations are first transformed into vectors of their functional values of length d corresponding to equi-spaced points in the domain given by the interval range. Functional values in these points are reconstructed using linear interpolation, and extrapolation.
q	The quantile presenting a threshold for the first order outlier detection. Functions with first order integrated depth smaller than the q quantile of this sample of depths are flagged as potential outliers. If set to NULL, the the outliers are detected from the first order integrated depth after the log-transformation, as for higher order outliers.

method	The depth that is used in the diagnostic plot. possible values are halfspace for the halfspace depth, or simplicial for the simplicial depth.
approx	For the computation of the third order integrated depth, the number of approximations used in the computation of the order extended depth. By default this is set to 100, meaning that 100 trivariate points are randomly sampled in unit cube, and at these points the trivariate depths of the corresponding functional values. May be set to 0 to compute the depth at all possible d^3 combinations of the points in the domain. This choice may result in very slow computation, see also depthf.fd1.
print	If the rows of X are named, print=TRUE enables a graphical output when the names of the outlying curves are displayed.
plotpairs	If set to TRUE, the scatter plot of the computed depths for orders 1, 2 and 3 is is displayed. Here, the depths corresponding to the flagged outliers are plotted in colour.
max.order	Maximal order of shape outlyingness to be computed, can be set to 1, 2, or 3.
exclude.out	Logical variable; exclude the detected lower order outliers in the flagging process? By default TRUE.
output	Output method, can be set to matrix for a matrix with logical entries (TRUE for outliers), or list for a list of outliers.
identifiers	A vector of names for the data observations. Facilitates identification of outlying functions.

Details

Using the procedure described in Nagy et al. (2016), the function uses the order extended integrated depths for functions, see depthf.fd1 and shape.fd.analysis, to perform informal functional shape outlier detection. Outliers of the first order (horizontal shift outliers) are found as the functions with q % of smallest (first order) integrated depth values. Second and third order outliers (shape outliers) are found using the extension of the boxplot method for depths as described in the paper Nagy et al. (2016).

Value

A matrix of logical values of size n*4, where n is the sample size. In the first three rows indicators of outlyingness of the corresponding functions for orders 1, 2 and 3 are given, in the fourth row the indicator of outlyingness with respect to the comparison of the first, and third order depths is given. That is, the fist row corresponds to the first order outliers, the second row to the second order outliers, and the last two rows formally to the third order outliers. Please consult Nagy et al. (2016) to interpret the notion of shape outlyingness.
