gets-package

General-to-Specific Modelling and Indicator Saturation Methods

Description

Multi-path General-to-Specific (GETS) modelling of the mean and/or variance of a regression, and Indicator Saturation (ISAT) methods for detecting structural breaks in the mean. The mean can be specified as an autoregressive model with covariates (an 'AR-X' model), and the variance can be specified as a dynamic log-variance model with covariates (a 'log-ARCH-X' model). For the statistical details of the model, see Section 4 in Pretis, Reade and Sucarrat (2018).

The main functions of the package are `arx`, `getsm`, `getsv` and `isat`. The first function, `arx`, estimates an AR-X model with (optionally) a log-ARCH-X specification on the log-variance. The second function, `getsm`, undertakes GETS model selection of the mean specification of an `arx` object. The third function, `getsv`, undertakes GETS model selection of the log-variance specification of an `arx` object. The fourth function, `isat`, undertakes GETS model selection of an indicator saturated mean specification. Extraction functions (mainly S3 methods) are also available, together with additional auxiliary functions used by the main functions.

For an introduction to the package, see Pretis, Reade and Sucarrat (2018): <https://www.jstatsoft.org/article/view/v086i03>. The package also provides facilities for user-defined GETS and ISAT methods. While this is to some extent available via the main functions, full flexibility is provided by `getsFun` and `blocksFun`, see Sucarrat (2019): <https://mpra.ub.uni-muenchen.de/96653/>.

Details

Package: gets
Type: Package
Version: 0.25
Date: 2020-08-11
License: GPL-2

The code originated in relation with G. Sucarrat and A. Escribano (2012). Felix Pretis and James Reade joined for the development of the `isat` code and related functions. Subsequently, Moritz Schwarz and Jonas Kurle have made various contributions.

Examples

```
##Simulate from an AR(1):
set.seed(123)
y <- arima.sim(list(ar=0.4), 60)

##Estimate an AR(2) with intercept as mean specification
##and a log-ARCH(4) as log-volatility specification:
myModel <- arx(y, mc=TRUE, ar=1:2, arch=1:4)

##GETS modelling of the mean of myModel:
simpleMean <- getsm(myModel)

##GETS modelling of the log-variance of myModel:
simpleVar <- getsv(myModel)

##results:
print(simpleMean)
print(simpleVar)

##step indicator saturation of an iid normal series:
set.seed(123)
y <- rnorm(30)
isat(y)
```

arx

Estimate an AR-X model with log-ARCH-X errors

Description

Estimation by OLS, two-step OLS if a variance specification is specified: In the first the mean specification (AR-X) is estimated, whereas in the second step the log-variance specification (log-ARCH-X) is estimated.

The AR-X mean specification can contain an intercept, AR-terms, lagged moving averages of the regressand and other conditioning covariates ('X'). The log-variance specification can contain log-ARCH terms, asymmetry or 'leverage' terms, log(EqWMA) where EqWMA is a lagged equally weighted moving average of past squared residuals (a volatility proxy) and other conditioning covariates ('X').

Usage

```
arx(y, mc=FALSE, ar=NULL, ewma=NULL, mxreg=NULL, vc=FALSE,
    arch=NULL, asym=NULL, log.ewma=NULL, vxreg=NULL, zero.adj=0.1,
    vc.adj=TRUE, vcov.type=c("ordinary", "white", "newey-west"),
    qstat.options=NULL, normality.JarqueB=FALSE, user.estimate=NULL,
    user.diagnostics=NULL, tol=1e-07, LAPACK=FALSE, plot=NULL)
```

Arguments

y	numeric vector, time-series or zoo object. Missing values in the beginning and at the end of the series is allowed, as they are removed with the na.trim command
mc	logical. TRUE includes an intercept in the mean specification, whereas FALSE (default) does not
ar	either NULL (default) or an integer vector, say, <code>c(2,4)</code> or <code>1:4</code> . The AR-lags to include in the mean specification. If NULL, then no lags are included
ewma	either NULL (default) or a list with arguments sent to the eqwma function. In the latter case a lagged moving average of y is included as a regressor
mxreg	either NULL (default) or a numeric vector or matrix, say, a zoo object, of conditioning variables. Note that, if both y and mxreg are zoo objects, then their samples are chosen to match
vc	logical. TRUE includes an intercept in the log-variance specification, whereas FALSE (default) does not. If the log-variance specification contains any other item but the log-variance intercept, then vc is set to TRUE
arch	either NULL (default) or an integer vector, say, <code>c(1,3)</code> or <code>2:5</code> . The log-ARCH lags to include in the log-variance specification
asym	either NULL (default) or an integer vector, say, <code>c(1)</code> or <code>1:3</code> . The asymmetry (i.e. 'leverage') terms to include in the log-variance specification
log.ewma	either NULL (default) or a vector of the lengths of the volatility proxies, see leqwma
vxreg	either NULL (default) or a numeric vector or matrix, say, a zoo object, of conditioning variables. If both y and mxreg are zoo objects, then their samples are chosen to match
zero.adj	numeric value between 0 and 1. The quantile adjustment for zero values. The default 0.1 means the zero residuals are replaced by the 10 percent quantile of the absolute residuals before taking the logarithm
vc.adj	logical. If TRUE (default), then the log-variance intercept is adjusted by the estimate of $E[\ln(z^2)]$, where z is the standardised error. This adjustment is needed for the conditional scale to be equal to the conditional standard deviation. If FALSE, then the log-variance intercept is not adjusted
vcov.type	character vector, "ordinary" (default), "white" or "newey-west". If "ordinary", then the ordinary variance-covariance matrix is used for inference. If "white", then the White (1980) heteroscedasticity-robust matrix is used. If "newey-west", then the Newey and West (1987) heteroscedasticity and autocorrelation-robust matrix is used

<code>qstat.options</code>	NULL (default) or an integer vector of length two, say, <code>c(1,1)</code> . The first value sets the lag-order of the AR diagnostic test, whereas the second value sets the lag-order of the ARCH diagnostic test. If NULL, then the two values of the vector are set automatically
<code>normality.JarqueB</code>	FALSE (default) or TRUE. If TRUE, then the results of the Jarque and Bera (1980) test for non-normality in the residuals are included in the estimation results.
<code>user.estimate</code>	NULL (default) or a list with one entry, <code>name</code> , containing the name of the user-defined estimator. Additional items, if any, are passed on as arguments to the estimator in question
<code>user.diagnostics</code>	NULL (default) or a list with two entries, <code>name</code> and <code>pval</code> , see the <code>user.fun</code> argument in diagnostics
<code>tol</code>	numeric value (default = $1e-07$). The tolerance for detecting linear dependencies in the columns of the regressors (see qr function). Only used if LAPACK is FALSE (default) and <code>user.estimate</code> is NULL.
LAPACK	logical. If TRUE, then use LAPACK. If FALSE (default), then use LINPACK (see qr function). Only used if <code>user.estimate</code> is NULL.
<code>plot</code>	NULL or logical. If TRUE, then the fitted values and the residuals are plotted. If NULL (default), then the value set by options determines whether a plot is produced or not.

Details

For an overview of the AR-X model with log-ARCH-X errors, see Pretis, Reade and Sucarrat (2018): <https://www.jstatsoft.org/article/view/v086i03>.

The arguments `user.estimate` and `user.diagnostics` enables the specification of user-defined estimators and user-defined diagnostics. To this end, the principles of the same arguments in [getsFun](#) are followed, see its documentation under "Details", and Sucarrat (2019): <https://mpra.ub.uni-muenchen.de/96653/>.

Value

A list of class 'arx'

```

biascorr	<i>Bias-correction of coefficients following general-to-specific model selection</i>
----------	--

Description

Takes a vector of coefficients (valid for orthogonal variables), their standard errors, the significance level the variables were selected at, and the sample size, to return bias-corrected coefficient estimates to account for the bias induced by model selection.

Usage

```
biascorr(b, b.se, p.alpha, T)
```

Arguments

b	a Kx1 vector of coefficients.
b.se	a Kx1 vector of standard errors of the coefficients in 'b'.
p.alpha	numeric value between 0 and 1, the significance level at which selection was conducted.
T	integer, the sample size of the original model selection regression.

Details

The function computes the bias-corrected estimates of coefficients in regression models post general-to-specific model selection using the approach by Hendry and Krolzig (2005). The results are valid for orthogonal regressors only. Bias correction can be applied to the coefficient path in `isat` models where the only additional covariate besides indicators is an intercept - see Pretis (2015).

Value

Returns a Kx3 matrix, where the first column lists the original coefficients, the second column the one-step corrected coefficients, and the third column the two-step bias-corrected coefficients.

#var <- isatvar(isat.nile)
#biascorr(b=var$const.path, b.se=var$const.se, p.alpha=0.005, T=length(var$const.path))

##Bias-correction of the coefficient path on artificial data
#set.seed(123)
#d <- matrix(0,100,1)
#d[35:55] <- 1
#e <- rnorm(100, 0, 1)
#y <- d*1 +e

#ys <- isat(y, sis=TRUE, iis=FALSE, t.pval=0.01)
#var <- isatvar(ys)
#biascorr(b=var$const.path, b.se=var$const.se, p.alpha=0.01, T=length(var$const.path))
```

blocksFun

Block-based General-to-Specific (GETS) modelling

Description

Auxiliary function (i.e. not intended for the average user) that enables block-based GETS-modelling with user-specified estimators, diagnostics and goodness-of-fit criteria.

Usage

```
blocksFun(y, x, untransformed.residuals=NULL, blocks=NULL,
  no.of.blocks=NULL, max.block.size=30, ratio.threshold=0.8,
  gets.of.union=TRUE, force.invertibility=FALSE,
  user.estimate=list(name="ols"), t.pval=0.001, wald.pval=t.pval,
  do.pet=FALSE, ar.LjungB=NULL, arch.LjungB=NULL, normality.JarqueB=NULL,
  user.diagnostics=NULL, gof.function=list(name="infocrit"),
  gof.method=c("min", "max"), keep=NULL, include.gum=FALSE,
  include.1cut=FALSE, include.empty=FALSE, max.paths=NULL,
  turbo=FALSE, parallel.options=NULL, tol=1e-07, LAPACK=FALSE,
  max.regs=NULL, print.searchinfo=TRUE, alarm=FALSE)
```

Arguments

y a numeric vector (with no missing values, i.e. no non-numeric 'holes')

x a matrix, or a list of matrices

untransformed.residuals	NULL (default) or, when <code>ols</code> is used with <code>method=6</code> in <code>user.estimate</code> , a numeric vector containing the untransformed residuals
blocks	NULL (default) or a list of lists with vectors of integers that indicate how blocks should be put together. If NULL, then the block composition is undertaken automatically by an internal algorithm that depends on <code>no.of.blocks</code> , <code>max.block.size</code> and <code>ratio.threshold</code>
no.of.blocks	NULL (default) or integer. If NULL, then the number of blocks is determined automatically by an internal algorithm
max.block.size	integer that controls the size of blocks
ratio.threshold	numeric between 0 and 1 that controls the minimum ratio of variables in each block to total observations
gets.of.union	logical. If TRUE, then GETS modelling is undertaken of the union of retained variables. Otherwise it is not
force.invertibility	logical. If TRUE, then the x-matrix is ensured to have full row-rank before it is passed on to <code>getsFun</code>
user.estimate	list, see <code>getsFun</code> for the details
t.pval	numeric value between 0 and 1. The significance level used for the two-sided coefficient significance t-tests
wald.pval	numeric value between 0 and 1. The significance level used for the Parsimonious Encompassing Tests (PETs)
do.pet	logical. If TRUE, then a Parsimonious Encompassing Test (PET) against the GUM is undertaken at each variable removal for the joint significance of all the deleted regressors along the current GETS path. If FALSE, then a PET is not undertaken at each removal
ar.LjungB	a two element vector, or NULL. In the former case, the first element contains the AR-order, the second element the significance level. If NULL, then a test for autocorrelation in the residuals is not conducted
arch.LjungB	a two element vector, or NULL. In the former case, the first element contains the ARCH-order, the second element the significance level. If NULL, then a test for ARCH in the residuals is not conducted
normality.JarqueB	NULL or a numeric value between 0 and 1. In the latter case, a test for non-normality in the residuals is conducted using a significance level equal to <code>normality.JarqueB</code> . If NULL, then no test for non-normality is conducted
user.diagnostics	NULL (default) or a list with two entries, <code>name</code> and <code>pval</code> . See <code>getsFun</code> for the details
gof.function	list. The first item should be named <code>name</code> and contain the name (a character) of the Goodness-of-Fit (GOF) function used. Additional items in the list <code>gof.function</code> are passed on as arguments to the GOF-function. . See <code>getsFun</code> for the details

<code>gof.method</code>	character. Determines whether the best Goodness-of-Fit is a minimum (default) or maximum
<code>keep</code>	NULL (default), vector of integers or a list of vectors of integers. In the latter case, the number of vectors should be equal to the number of matrices in <code>x</code>
<code>include.gum</code>	logical. If TRUE, then the GUM (i.e. the starting model) is included among the terminal models
<code>include.1cut</code>	logical. If TRUE, then the 1-cut model is added to the list of terminal models
<code>include.empty</code>	logical. If TRUE, then the empty model is added to the list of terminal models
<code>max.paths</code>	NULL (default) or integer greater than 0. If NULL, then there is no limit to the number of paths. If integer (e.g. 1), then this integer constitutes the maximum number of paths searched (e.g. a single path)
<code>turbo</code>	logical. If TRUE, then (parts of) paths are not searched twice (or more) unnecessarily in each GETS modelling. Setting turbo to TRUE entails a small additional computational costs, but may be outweighed substantially if estimation is slow, or if the number of variables to delete in each path is large
<code>parallel.options</code>	NULL or integer that indicates the number of cores/threads to use for parallel computing (implemented w/makeCluster and parLapply)
<code>tol</code>	numeric value, the tolerance for detecting linear dependencies in the columns of the variance-covariance matrix when computing the Wald-statistic used in the Parsimonious Encompassing Tests (PETs), see the qr.solve function
LAPACK	currently not used
<code>max.regs</code>	integer. The maximum number of regressions along a deletion path. Do not alter unless you know what you are doing!
<code>print.searchinfo</code>	logical. If TRUE (default), then a print is returned whenever simplification along a new path is started
<code>alarm</code>	logical. If TRUE, then a sound or beep is emitted (in order to alert the user) when the model selection ends

Details

blocksFun undertakes block-based GETS modelling by a repeated but structured call to `getsFun`. For the details of how to user-specify an estimator via `user.estimator`, diagnostics via `user.diagnostics` and a goodness-of-fit function via `gof.function`, see documentation of [getsFun](#) under "Details".

The algorithm of blocksFun is similar to that of [isat](#), but more flexible. The main use of blocksFun is the creation of user-specified methods that employs block-based GETS modelling, e.g. indicator saturation techniques.

Value

A [list](#) with the results of the block-based GETS-modelling.

```

coef.arx

Extraction functions for 'arx' objects

Description

Extraction functions for objects of class 'arx'

Usage

```
## S3 method for class 'arx'
coef(object, spec=NULL, ...)
## S3 method for class 'arx'
fitted(object, spec=NULL, ...)
## S3 method for class 'arx'
logLik(object, ...)
## S3 method for class 'arx'
plot(x, spec=NULL, col=c("red","blue"),
     lty=c("solid","solid"), lwd=c(1,1), ...)
## S3 method for class 'arx'
print(x, signif.stars=TRUE, ...)
## S3 method for class 'arx'
```

```

residuals(object, std=FALSE, ...)
  ## S3 method for class 'arx'
sigma(object, ...)
  ## S3 method for class 'arx'
summary(object, ...)
  ## S3 method for class 'arx'
vcov(object, spec=NULL, ...)

```

Arguments

object	an object of class 'arx'
x	an object of class 'arx'
spec	NULL, "mean", "variance" or, in some instances, "both". When NULL is a valid value, then it is automatically determined whether information pertaining to the mean or variance specification should be returned
signif.stars	logical. If TRUE, then p-values are additionally encoded visually, see printCoefmat
std	logical. If FALSE (default), then the mean residuals are returned. If TRUE, then the standardised residuals are returned
col	colours of actual (default=blue) and fitted (default=red) lines
lty	types of actual (default=solid) and fitted (default=solid) lines
lwd	widths of actual (default=1) and fitted (default=1) lines
...	additional arguments

Value

coef:	a numeric vector containing parameter estimates
fitted:	a zoo object with fitted values
logLik:	log-likelihood (normal density)
plot:	a plot of the fitted values and the residuals
print:	a print of the estimation results
residuals:	a zoo object with the residuals
sigma:	the regression standard error ('SE of regression')
summary:	a print of the items in the arx object
vcov:	variance-covariance matrix

coef.gets

Extraction functions for 'gets' objects

Description

Extraction functions for objects of class 'gets'

Usage

```

## S3 method for class 'gets'
coef(object, spec=NULL, ...)
## S3 method for class 'gets'
fitted(object, spec=NULL, ...)
## S3 method for class 'gets'
logLik(object, ...)
## S3 method for class 'gets'
plot(x, spec=NULL, col=c("red","blue"),
      lty=c("solid","solid"), lwd=c(1,1), ...)
## S3 method for class 'gets'
predict(object, spec=NULL, n.ahead=12, newmxreg=NULL,
         newvxreg=NULL, newindex=NULL, n.sim=5000, innov=NULL, probs=NULL,
         ci.levels=NULL, quantile.type=7, return=TRUE, verbose=FALSE, plot=NULL,
         plot.options=list(), ...)
## S3 method for class 'gets'
print(x, signif.stars=TRUE, ...)
## S3 method for class 'gets'
residuals(object, std=NULL, ...)
## S3 method for class 'gets'
sigma(object, ...)
## S3 method for class 'gets'

```

```
summary(object, ...)
## S3 method for class 'gets'
vcov(object, spec=NULL, ...)
```

Arguments

object	an object of class 'gets'
x	an object of class 'gets'
spec	NULL, "mean", "variance" or, in some instances, "both". When NULL is a valid value, then it is automatically determined whether information pertaining to the mean or variance specification should be returned
signif.stars	logical. If TRUE, then p-values are additionally encoded visually, see printCoefmat
std	logical. If FALSE (default), then the mean residuals are returned. If TRUE, then the standardised residuals are returned
n.ahead	integer that determines how many steps ahead predictions should be generated (the default is 12)
newmxreg	a matrix of n.ahead rows and NCOL(mxreg) columns with the out-of-sample values of the mxreg regressors
newvxreg	a matrix of n.ahead rows and NCOL(vxreg) columns with the out-of-sample values of the vxreg regressors
newindex	NULL (default) or the date-index for the zoo object returned by predict.ar.x. If NULL, then the function uses the in-sample index to generate the out-of-sample index
n.sim	integer, the number of replications used for the generation of the forecasts
innov	NULL (default) or a vector of length n.ahead * n.sim containing the standardised errors (that is, zero mean and unit variance) used for the forecast simulations. If NULL, then a classical bootstrap procedure is used to draw from the standardised in-sample residuals
probs	NULL (default) or a vector with the quantile-levels (values strictly between 0 and 1) of the forecast distribution. If NULL, then no quantiles are returned unless ci.levels is non-NULL
ci.levels	NULL (default) or a vector with the confidence levels (expressed as values strictly between 0 and 1) of the forecast distribution. The upper and lower values of the confidence interval(s) are returned as quantiles
quantile.type	an integer between 1 and 9 that selects which algorithm to be used in computing the quantiles, see the argument type in quantile
return	logical. If TRUE (default), then the out-of-sample predictions are returned. The value FALSE, which does not return the predictions, may be of interest if only a prediction plot is of interest
verbose	logical with default FALSE. If TRUE, then additional information (typically the quantiles and/or the simulated series) used in the generation of forecasts is returned. If FALSE, then only the forecasts are returned
plot	NULL (default) or logical. If NULL, then the value set by options\$plot (see options) determines whether a plot is produced or not. If TRUE, then the out-of-sample forecasts are plotted.

plot.options	a list of options related to the plotting of forecasts, see 'Details'
col	colours of fitted (default=red) and actual (default=blue) lines
lty	types of fitted (default=solid) and actual (default=solid) lines
lwd	widths of fitted (default=1) and actual (default=1) lines
...	additional arguments

Details

The `plot.options` argument is a list that controls the prediction plot, see 'Details' in [predict.arx](#)

Value

coef:	a numeric vector containing parameter estimates
fitted:	a <code>zoo</code> object with fitted values
logLik:	a numeric, the log-likelihood (normal density)
plot:	a plot of the fitted values and the residuals
predict:	a vector of class <code>zoo</code> containing the out-of-sample forecasts, or a matrix of class <code>zoo</code> containing the out-of-sample forecasts together with prediction-quantiles, or - if <code>return=FALSE</code> - NULL
print:	a print of the estimation results
residuals:	a <code>zoo</code> object with the residuals
sigma:	the regression standard error ('SE of regression')
summary:	a print of the items in the <code>gets</code> object
vcov:	a variance-covariance matrix

## S3 method for class 'isat'
residuals(object, std=FALSE, ...)
## S3 method for class 'isat'
sigma(object, ...)
## S3 method for class 'isat'
summary(object, ...)
## S3 method for class 'isat'
vcov(object, ...)
```

Arguments

object	an object of class 'isat'
x	an object of class 'isat'
std	logical. If FALSE (default), then the mean residuals are returned. If TRUE, then the standardised residuals are returned
n.ahead	integer that determines how many steps ahead predictions should be generated (the default is 12)
newmxreg	a matrix of n.ahead rows and NCOL(mxreg) columns with the out-of-sample values of the mxreg regressors
newindex	NULL (default) or the date-index for the zoo object returned by predict.arx. If NULL, then the function uses the in-sample index to generate the out-of-sample index
n.sim	integer, the number of replications used for the generation of the forecasts

probs	NULL (default) or a vector with the quantile-levels (values strictly between 0 and 1) of the forecast distribution. If NULL, then no quantiles are returned unless <code>ci.levels</code> is non-NULL
ci.levels	NULL (default) or a vector with the confidence levels (expressed as values strictly between 0 and 1) of the forecast distribution. The upper and lower values of the confidence interval(s) are returned as quantiles
quantile.type	an integer between 1 and 9 that selects which algorithm to be used in computing the quantiles, see the argument <code>type</code> in quantile
return	logical. If TRUE (default), then the out-of-sample predictions are returned. The value FALSE, which does not return the predictions, may be of interest if only a prediction plot is of interest
verbose	logical with default FALSE. If TRUE, then additional information (typically the quantiles and/or the simulated series) used in the generation of forecasts is returned. If FALSE, then only the forecasts are returned
plot	NULL (default) or logical. If NULL, then the value set by <code>options\$plot</code> (see options) determines whether a plot is produced or not. If TRUE, then the out-of-sample forecasts are plotted.
plot.options	a list of options related to the plotting of forecasts, see 'Details'
col	colours of fitted (default=red) and actual (default=blue) lines
lty	types of fitted (default=solid) and actual (default=solid) lines
lwd	widths of fitted (default=1) and actual (default=1) lines
coef.path	logical. Only applicable if there are retained indicators after the application of <code>isat</code>
signif.stars	logical. If TRUE, then p-values are additionally encoded visually, see printCoefmat
...	additional arguments

Details

The `plot.options` argument is a list that controls the prediction plot, see 'Details' in [predict.arx](#)

Value

coef:	numeric vector containing parameter estimates
fitted:	a zoo object with fitted values
logLik:	a numeric, the log-likelihood (normal density)
plot:	plot of the fitted values and the residuals
predict:	a vector of class zoo containing the out-of-sample forecasts, or a matrix of class zoo containing the out-of-sample forecasts together with prediction-quantiles, or - if <code>return=FALSE</code> - NULL
print:	a print of the estimation results
residuals:	a zoo object with the residuals
sigma:	the regression standard error ('SE of regression')
summary:	a print of the items in the isat object
vcov:	variance-covariance matrix

```

diagnostics

*Diagnostics tests***Description**

Auxiliary function (i.e. not intended for the average user) called by the `arx`, `getsm`, `getsv`, `isat`, `getsFun` and `blocksFun` functions. The `diagnostics` function undertakes tests for autocorrelation, ARCH and non-normality in a residual series, and user-defined diagnostics provided via the `user.fun` argument (see details). The autocorrelation and ARCH tests are conducted as Ljung and Box (1979) tests for autocorrelation in the residuals and squared residuals, respectively, whereas the test for non-normality is that of Jarque and Bera (1980).

Usage

```
diagnostics(x, ar.LjungB=c(1, 0.025), arch.LjungB=c(1, 0.025),
            normality.JarqueB=NULL, verbose=TRUE, user.fun=NULL, ...)
```

Arguments

<code>x</code>	a list , for example the estimation result of <code>ols</code> . The tests for serial correlation, ARCH and normality look for an entry in the list named <code>std.residuals</code> or <code>residuals</code>
<code>ar.LjungB</code>	a two element vector or <code>NULL</code> . In the former case, the first element contains the AR-order, the second element the significance level. If <code>NULL</code> , then a test for autocorrelation is not conducted
<code>arch.LjungB</code>	a two element vector or <code>NULL</code> . In the former case, the first element contains the ARCH-order, the second element the significance level. If <code>NULL</code> , then a test for ARCH is not conducted
<code>normality.JarqueB</code>	<code>NULL</code> (the default) or a value between 0 and 1. In the latter case, a test for non-normality is conducted using a significance level equal to <code>normality.JarqueB</code> . If <code>NULL</code> , then no test for non-normality is conducted
<code>verbose</code>	logical. If <code>TRUE</code> , then a data.frame with the results of the diagnostics is returned. If <code>FALSE</code> , then the return-value is a logical that indicates whether the model passes the diagnostics (<code>TRUE</code> if it does, otherwise <code>FALSE</code>)
<code>user.fun</code>	<code>NULL</code> or a list with at least one entry, <code>name</code> (must be of class character), which should contain the name of the user-defined function. See details
<code>...</code>	further arguments (ignored) to accommodate deleted arguments from past versions of the functions

Details

The argument `user.fun` enables the user to specify additional diagnostics. To do this, the argument should be a **list** with at least one entry, `name` (of class character), that contains the name of the user-defined function. The call to this function is executed with `do.call`, whose default value on

`envir` is `parent.frame()`. Usually, this will be the global environment (`.GlobalEnv`), but it can be changed by adding an entry named `envir` to the list that indicates where the user-defined function resides. If the `verbose` argument is set to `FALSE`, then an entry named `pval` must be provided. This entry should contain the chosen significance level or levels, i.e. either a scalar or a vector of length equal to the number of p -values returned by the user-defined diagnostics function (see examples). Additional entries in the `list` are passed on as arguments to the user-defined function.

The user-defined function should refer to the named items of the estimation result `x` (see examples), and the value returned by the user-defined function should be a matrix of dimension $m \times 3$. Here, m is the number of diagnostic tests performed by the user-defined function. For example, if only a single test is performed, then $m = 1$ and so the returned value should be a 1×3 matrix (or a vector of length 3). The three columns of the $m \times 3$ matrix should contain, in the following order, 1) the value(s) of the test-statistic(s) (or NA), 2) the degree(s) of freedom(s) (or NA) of the tests, and 3) the p -value(s) of the test(s). When checking whether the model passes the diagnostics or not, the p -value(s) is(are) checked against the value(s) in the entry named `pval` in the `list` provided to `user.fun`.

Value

If `verbose=TRUE`:

a `data.frame` that contains the diagnostics results

If `verbose=FALSE`:

a logical indicating whether the residuals and/or model passes ALL the diagnostics (TRUE if it does, FALSE otherwise)

diagnostics(est, user.fun=list(name="SWtest", pval=0.05), verbose=FALSE)

```

dropvar

Drop variable

Description

Drops columns in a matrix to avoid perfect multicollinearity.

Usage

```
dropvar(x, tol=1e-07, LAPACK=FALSE, silent=FALSE)
```

Arguments

x	a matrix, possibly less than full column rank.
tol	numeric value. The tolerance for detecting linear dependencies among regressors, see qr function. Only used if LAPACK is FALSE
LAPACK	logical, TRUE or FALSE (default). If true use LAPACK otherwise use LINPACK, see qr function
silent	logical, TRUE (default) or FALSE. Whether to print a notification whenever a regressor is removed

Details

Original function `drop.coef` developed by Rune Haubo B. Christensen in package `ordinal`, <https://cran.r-project.org/package=ordinal>.

Value

a matrix whose regressors linearly independent

Author(s)

Rune Haubo B. Christensen, with modifications by Genaro Sucarrat, <http://www.sucarrat.net/>

dropvar(x) #full rank, none are dropped

x[,4] <- x[,1]*2
dropvar(x) #less than full rank, last column dropped
```

eqwma	<i>Equally Weighted Moving Average (EqWMA) of the pth. exponentiated values</i>
-------	---

Description

The function `eqwma` returns an Equally Weighted Moving Average (EqWMA) of the `pth.` exponentiated values lagged `k` times (the default of `k` is 1). Optionally, the absolute values are computed before averaging if `abs=TRUE`, and the natural log of the values is returned if `log=TRUE`. The function `leqwma` is a wrapper to `eqwma` with `abs=TRUE` and `log=TRUE`.

If `x` is financial return (possibly mean-corrected) and `p=2`, then this gives the so-called 'historical' model, also known as an integrated ARCH model where the ARCH coefficients all have the same value with sum equal to one. In the log-variance specification the lag of `log(EqWMA)` is thus a financial volatility proxy. It may be an imperfect proxy compared with high-frequency data (which can also be included as regressors), but - in contrast to high-frequency data - is always available and easy to compute.

Usage

```
eqwma(x, length=5, k=1, p=1, abs=FALSE, log=FALSE, as.vector=FALSE,
      lag=NULL, start=NULL)
leqwma(x, length=5, k=1, p=2, as.vector=FALSE, lag=NULL, start=NULL)
```

Arguments

<code>x</code>	numeric vector, time-series or zoo object
<code>length</code>	integer or vector of integers each equal to or greater than 1. The length or lengths of the moving window or windows of averages
<code>k</code>	integer that determines how many periods the term(s) should be lagged. If 0 (or smaller), then the moving averages are not lagged

p	numeric value. The exponent p in x^p when <code>abs=FALSE</code> , and in $\text{abs}(x)^p$ when <code>abs=TRUE</code>
log	logical with default <code>FALSE</code> . If <code>TRUE</code> , then the logarithm of the moving average is returned
abs	logical with default <code>FALSE</code> . If <code>TRUE</code> , then x is transformed to absolute values before x is exponentiated
as.vector	logical with default <code>FALSE</code> . If <code>TRUE</code> , and if <code>length(length)==1</code> , then the result is returned as a vector. Otherwise the returned value is always a matrix
lag	deprecated
start	deprecated

Details

The intended primary use of `eqwma` is to construct mixed frequency regressors for the mean specification of an `arx` model.

The intended primary use of `leqwma` is to construct volatility proxies for the log-variance specification in an `arx` model. In the latter case, the default is the lagged log of an equally weighted moving average of the squared residuals, where each average is made up of m observations. This is equivalent to an integrated ARCH(p) model where the p coefficients are all equal. For further details on the use of `log(EqWMA)` as a volatility proxy, see Sucarrat and Escribano (2012).

Value

numeric matrix, vector or `zoo` object

eqwma(x, length=c(5,10))

##compute lag of log(EqWMA(20)) for x^2:
leqwma(x)

#compute lag of log(EqWMA(5)) and lag of log(EqWMA(8))
#for abs(x)^2:
leqwma(x, length=c(4,8))
```

ES

Conditional Value-at-Risk (VaR) and Expected Shortfall (ES)

Description

Extract the in-sample conditional Value-at-Risk, or the in-sample conditional Expected Shortfall for the chosen risk level(s).

Usage

```
ES(object, level=0.99, type=7, ...)
VaR(object, level=0.99, type=7, ...)
```

Arguments

object	an <code>arx</code> or gets object
level	the risk level(s), must be between 0 and 1
type	the method used to compute the empirical quantiles of the standardised residuals
...	arguments passed on (currently not used)

Value

A vector or matrix containing either the conditional Value-at-Risk (VaR) or the conditional Expected Shortfall (ES) for the chosen risk level(s).

Author(s)

Genaro Sucarrat, <http://www.sucarrat.net/>

See Also

`arx`, `getsm`, `getsv`

Examples

##generate random variates, estimate model:
y <- rnorm(50)
mymodel <- arx(y, arch=1)

##extract 99% expected shortfall:
ES(mymodel)

##extract 99%, 95% and 90% expected shortfalls:
ES(mymodel, level=c(0.99, 0.95, 0.9))

##extract 99% value-at-risk:
VaR(mymodel)

##extract 99%, 95% and 90% values-at-risk:
VaR(mymodel, level=c(0.99, 0.95, 0.9))
```

eviews

Exporting results to EViews and STATA

Description

Functions that facilitate the export of results to the commercial econometric softwares EViews and STATA, respectively.

Usage

```
eviews(object, file=NULL, print=TRUE, return=FALSE)
stata(object, file=NULL, print=TRUE, return=FALSE)
```

Arguments

object	an arx, gets or isat object
file	filename, i.e. the destination of the exported data
print	logical. If TRUE, then the estimation code in EViews (or STATA) is printed
return	logical. If TRUE, then a list is returned

Value

Either printed text or a list (if return=TRUE)

Author(s)

Genaro Sucarrat, <http://www.sucarrat.net/>

mymod <- arx(y, mc=TRUE, mxreg=mX)

##print EViews code:
eviews(mymod)

##print Stata code:
stata(mymod)
```

 gets

General-to-Specific (GETS) Modelling

Description

Generic function that enables new GETS and ISAT methods for new classes

Usage

```
gets(x, ...)
```

##wrapper to getsm() and getsv():
S3 method for class 'arx'
gets(x, spec=NULL, ...)

Arguments

x	an object of class 'arx' used to select a method
...	further arguments passed to or from other methods
spec	NULL (default), "mean" or "variance". If "mean", then getsm is called. If "variance", then getsv is called. If NULL, then it is automatically determined whether GETS-modelling of the mean or log-variance specification should be undertaken.

Details

gets.arx is a convenience wrapper to [getsm](#) and [getsv](#).

Author(s)

Genaro Sucarrat, <http://www.sucarrat.net/>

See Also

[getsm](#), [getsv](#), [getsFun](#)

 getsFun

General-to-Specific (GETS) modelling function

Description

Auxiliary function (i.e. not intended for the average user) that enables fast and efficient GETS-modelling with user-specified estimators and models, and user-specified diagnostics and goodness-of-fit criteria. The function is called by and relied upon by [getsm](#), [getsv](#), [isat](#) and [blocksFun](#).

Usage

```
getsFun(y, x, untransformed.residuals=NULL,
        user.estimator=list(name="ols"), gum.result=NULL, t.pval=0.05,
        wald.pval=t.pval, do.pet=TRUE, ar.LjungB=NULL, arch.LjungB=NULL,
        normality.JarqueB=NULL, user.diagnostics=NULL,
        gof.function=list(name="infocrit"), gof.method=c("min", "max"),
        keep=NULL, include.gum=FALSE, include.1cut=FALSE,
        include.empty=FALSE, max.paths=NULL, turbo=FALSE, tol=1e-07,
        LAPACK=FALSE, max.regs=NULL, print.searchinfo=TRUE, alarm=FALSE)
```

Arguments

<code>y</code>	a numeric vector (with no missing values, i.e. no non-numeric 'holes')
<code>x</code>	a matrix or NULL
<code>untransformed.residuals</code>	NULL (default) or, when <code>ols</code> is used with <code>method=6</code> in <code>user.estimator</code> , a numeric vector containing the untransformed residuals
<code>user.estimator</code>	a list. The first item should be named <code>name</code> and contain the name (a character) of the estimation function (the default is "ols"). Additional items, if any, in the list <code>user.estimator</code> are passed on as arguments to the estimator in question. Optionally, the list can also contain an item named <code>envir</code> , a character, which indicates the environment in which the user-specified estimator resides. The value returned by the user-specified estimator should be a list, see details
<code>gum.result</code>	a list with the estimation results of the General Unrestricted Model (GUM), or NULL (default). If the estimation results of the GUM are already available, then re-estimation of the GUM is skipped if the estimation results are provided via this argument
<code>t.pval</code>	numeric value between 0 and 1. The significance level used for the two-sided regressor significance t-tests
<code>wald.pval</code>	numeric value between 0 and 1. The significance level used for the Parsimonious Encompassing Tests (PETs)
<code>do.pet</code>	logical. If TRUE (default), then a Parsimonious Encompassing Test (PET) against the GUM is undertaken at each regressor removal for the joint significance of all the deleted regressors along the current path. If FALSE, then a PET is not undertaken at each regressor removal

<code>ar.LjungB</code>	a two element vector or NULL (default). In the former case, the first element contains the AR-order, the second element the significance level. If NULL, then a test for autocorrelation is not conducted
<code>arch.LjungB</code>	a two element vector or NULL (default). In the former case, the first element contains the ARCH-order, the second element the significance level. If NULL, then a test for ARCH is not conducted
<code>normality.JarqueB</code>	NULL or a numeric value between 0 and 1. In the latter case, a test for non-normality is conducted using a significance level equal to <code>normality.JarqueB</code> . If NULL, then no test for non-normality is conducted
<code>user.diagnostics</code>	NULL (default) or a list with two entries, <code>name</code> and <code>pval</code> . The first item (<code>name</code>) should contain the name of the user-defined function, and must be of class <code>character</code> . The second item should contain the chosen significance level or levels, i.e. either a scalar or a vector of length equal to the number of p-values returned by the user-defined diagnostics function, see details. Optionally, the list <code>user.diagnostics</code> can also contain a third item named <code>envir</code> , a character, which indicates the environment in which the user-defined function resides
<code>gof.function</code>	a list. The first item should be named <code>name</code> and contain the name (a character) of the Goodness-of-Fit (GOF) function used. Additional items in the list <code>gof.function</code> are passed on as arguments to the GOF-function. The value returned by the GOF-function should be a numeric value (of length 1). Optionally, the list <code>gof.function</code> can also contain an item named <code>envir</code> , a character, which indicates the environment in which the user-defined function resides
<code>gof.method</code>	a character. Determines whether the best Goodness-of-Fit is a minimum or maximum
<code>keep</code>	NULL or an integer vector that indicates which regressors to be excluded from removal in the search
<code>include.gum</code>	logical. If TRUE, then the GUM (i.e. the starting model) is included among the terminal models. If FALSE (default), then the GUM is not included
<code>include.1cut</code>	logical. If TRUE, then the 1-cut model is added to the list of terminal models. If FALSE (default), then the 1-cut is not added, unless it is a terminal model in one of the paths
<code>include.empty</code>	logical. If TRUE, then the empty model is added to the list of terminal models. If FALSE (default), then the empty model is not added, unless it is a terminal model in one of the paths
<code>max.paths</code>	NULL (default) or an integer greater than 0. If NULL, then there is no limit to the number of paths. If an integer (e.g. 1), then this integer constitutes the maximum number of paths searched (e.g. a single path)
<code>turbo</code>	logical. If TRUE, then (parts of) paths are not searched twice (or more) unnecessarily, thus yielding a significant potential for speed-gain. However, the checking of whether the search has arrived at a point it has already been comes with a slight computational overhead. Accordingly, if <code>turbo=TRUE</code> , then the total search time might in fact be higher than if <code>turbo=FALSE</code> . This happens if estimation is very fast, say, less than quarter of a second. Hence the default is FALSE

<code>tol</code>	numeric value (default = $1e-07$). The tolerance for detecting linear dependencies in the columns of the variance-covariance matrix when computing the Wald-statistic used in the Parsimonious Encompassing Tests (PETs), see the qr.solve function
<code>LAPACK</code>	currently not used
<code>max.regs</code>	integer. The maximum number of regressions along a deletion path. Do not alter unless you know what you are doing!
<code>print.searchinfo</code>	logical. If TRUE (default), then a print is returned whenever simplification along a new path is started
<code>alarm</code>	logical. If TRUE, then a sound or beep is emitted (in order to alert the user) when the model selection ends

Details

The value returned by the estimator specified in `user.estimator` should be a [list](#) containing at least six items: "coefficients", "df", "vcov", "logl", "n" and "k". The item "coefficients" should be a vector of length $NCOL(x)$ containing the estimated coefficients. The item named "df" is used to compute the p -values associated with the t -statistics, i.e. `coef/std.err`. The item named "vcov" contains the (symmetric) coefficient-covariance matrix of the estimated coefficients. The items "logl" (the log-likelihood), "n" (the number of observations) and "k" (the number of estimated parameters; not necessarily equal to the number of coefficients) are used to compute the information criterion. Finally, the estimator MUST be able to handle empty regressor-matrices (i.e. `is.null(x)=TRUE` or $NCOL(x)=0$). In this case, then the first three items (i.e. "coefficients", "df" and "vcov") can - and should - be NULL.

The argument `user.estimator` enables the user to specify an estimator that differs from the default ([ols](#)). To do this, the argument should be a list with at least one entry, name (of class character), that contains the name of the user-defined function. The call to this function is executed with [do.call](#), whose default value on `envir` is `parent.frame()`. Usually, this will be the global environment (`.GlobalEnv`), but it can be changed by adding an entry named `envir` to the list that indicates where the user-defined function resides.

The argument `user.diagnostics` enables the user to specify additional - or alternative - diagnostics, see [diagnostics](#).

The argument `gof.function` enables the user to specify a goodness-of-fit function that differs from the default ([infocrit](#)). The principles to follow are the same as that of `user.estimator`: The argument should be a list with at least one entry, name, that contains the name of the user-defined function, additional entries in the list are passed on to the user-specified goodness-of-fit function, and optionally an entry named `envir` may indicate where the user-defined function resides.

Value

A list with the results of the specification search.

```
##aim: do gets on the x-part (i.e. the covariates) of an arma-x model.
##create the user-defined estimator (essentially adding, renaming
##and re-organising the items returned by the estimator):
myEstimator <- function(y, x)
{
  tmp <- arima(y, order=c(1,0,1), xreg=x)

  #rename and re-organise:
  result <- list()
  result$coefficients <- tmp$coef[-c(1:3)]
  result$vcov <- tmp$var.coef
  result$vcov <- result$vcov[-c(1:3),-c(1:3)]
  result$loglik <- tmp$loglik
  result$n <- tmp$nobs
  result$k <- NCOL(x)
  result$df <- result$n - result$k

  return(result)
}

##generate some data:
##a series w/structural break and eleven step-dummies near the break
set.seed(123)
eps <- arima.sim(list(ar=0.4, ma=0.1), 60)
x <- coredata(sim(eps, which.ones=25:35)) #eleven step-dummies
y <- 4*x[, "sis30"] + eps #create shift upwards at observation 30
plot(y)

##estimate the gum and then do gets in a single step:
##getsFun(y, x, user.estimator=list(name="myEstimator"))

##estimate the gum and then do gets in two steps:
#mygum <- myEstimator(y, x)
```

```
##getsmFun(y, x, user.estimator=list(name="myEstimator"), gum.result=mygum)
```

getsm	<i>General-to-Specific (GETS) Modelling of an AR-X model (the mean specification) with log-ARCH-X errors (the log-variance specification).</i>
-------	--

Description

The starting model, an object of the 'arx' class, is referred to as the General Unrestricted Model (GUM). The getsm function undertakes multi-path GETS modelling of the mean specification, whereas getsv does the same for the log-variance specification. The diagnostic tests are undertaken on the standardised residuals, and the keep option enables regressors to be excluded from possible removal.

Usage

```
##GETS-modelling of mean specification:
getsm(object, t.pval=0.05, wald.pval=t.pval, vcov.type=NULL,
      do.pet=TRUE, ar.LjungB=list(lag=NULL, pval=0.025),
      arch.LjungB=list(lag=NULL, pval=0.025), normality.JarqueB=NULL,
      user.diagnostics=NULL, info.method=c("sc","aic","aicc", "hq"),
      gof.function=NULL, gof.method=NULL, keep=NULL, include.gum=FALSE,
      include.lcut=TRUE, include.empty=FALSE, max.paths=NULL, tol=1e-07,
      turbo=FALSE, print.searchinfo=TRUE, plot=NULL, alarm=FALSE)

##GETS modelling of log-variance specification:
getsv(object, t.pval=0.05, wald.pval=t.pval,
      do.pet=TRUE, ar.LjungB=list(lag=NULL, pval=0.025),
      arch.LjungB=list(lag=NULL, pval=0.025), normality.JarqueB=NULL,
      user.diagnostics=NULL, info.method=c("sc","aic","aicc","hq"),
      gof.function=NULL, gof.method=NULL, keep=c(1), include.gum=FALSE,
      include.lcut=TRUE, include.empty=FALSE, max.paths=NULL, tol=1e-07,
      turbo=FALSE, print.searchinfo=TRUE, plot=NULL, alarm=FALSE)
```

Arguments

object	an object of class 'arx'
t.pval	numeric value between 0 and 1. The significance level used for the two-sided regressor significance t-tests
wald.pval	numeric value between 0 and 1. The significance level used for the Parsimonious Encompassing Tests (PETs). By default, it is the same as t.pval
vcov.type	the type of variance-covariance matrix used. If NULL (default), then the type used in the estimation of the 'arx' object is used. This can be overridden by either "ordinary" (i.e. the ordinary variance-covariance matrix) or "white" (i.e. the White (1980) heteroscedasticity robust variance-covariance matrix)

<code>do.pet</code>	logical. If TRUE (default), then a Parsimonious Encompassing Test (PET) against the GUM is undertaken at each regressor removal for the joint significance of all the deleted regressors along the current path. If FALSE, then a PET is not undertaken at each regressor removal
<code>ar.LjungB</code>	a two-item list with names <code>lag</code> and <code>pval</code> , or NULL. In the former case <code>lag</code> contains the order of the Ljung and Box (1979) test for serial correlation in the standardised residuals, and <code>pval</code> contains the significance level. If <code>lag=NULL</code> (default), then the order used is that of the estimated 'arx' object. If <code>ar.Ljungb=NULL</code> , then the standardised residuals are not checked for serial correlation
<code>arch.LjungB</code>	a two-item list with names <code>lag</code> and <code>pval</code> , or NULL. In the former case, <code>lag</code> contains the order of the Ljung and Box (1979) test for serial correlation in the squared standardised residuals, and <code>pval</code> contains the significance level. If <code>lag=NULL</code> (default), then the order used is that of the estimated 'arx' object. If <code>arch.Ljungb=NULL</code> , then the standardised residuals are not checked for ARCH
<code>normality.JarqueB</code>	a value between 0 and 1, or NULL. In the former case, the Jarque and Bera (1980) test for non-normality is conducted using a significance level equal to the numeric value. If NULL, then no test for non-normality is undertaken
<code>user.diagnostics</code>	NULL or a list with two entries, <code>name</code> and <code>pval</code> , see the <code>user.fun</code> argument in diagnostics
<code>info.method</code>	character string, "sc" (default), "aic" or "hq", which determines the information criterion to be used when selecting among terminal models. The abbreviations are short for the Schwarz or Bayesian information criterion (sc), the Akaike information criterion (aic) and the Hannan-Quinn (hq) information criterion
<code>gof.function</code>	NULL (default) or a list , see getsFun . If NULL, then infocrit is used
<code>gof.method</code>	NULL (default) or a character, see getsFun . If NULL and <code>gof.function</code> is also NULL, then the best goodness-of-fit is characterised by a minimum value
<code>keep</code>	the regressors to be excluded from removal in the specification search. Note that <code>keep=c(1)</code> is obligatory when using <code>getsv</code> . This excludes the log-variance intercept from removal. The regressor numbering is contained in the <code>reg.no</code> column of the GUM
<code>include.gum</code>	logical. If TRUE, then the GUM (i.e. the starting model) is included among the terminal models. If FALSE (default), then the GUM is not included
<code>include.1cut</code>	logical. If TRUE, then the 1-cut model is added to the list of terminal models. If FALSE (default), then the 1-cut is not added, unless it is a terminal model in one of the paths
<code>include.empty</code>	logical. If TRUE, then an empty model is included among the terminal models, if it passes the diagnostic tests, even if it is not equal to one of the terminals. If FALSE (default), then the empty model is not included (unless it is one of the terminals)
<code>max.paths</code>	NULL (default) or an integer greater than 0. If NULL, then there is no limit to the number of paths. If an integer (e.g. 1), then this integer constitutes the maximum number of paths searched (e.g. a single path)

<code>tol</code>	numeric value. The tolerance for detecting linear dependencies in the columns of the variance-covariance matrix when computing the Wald-statistic used in the Parsimonious Encompassing Tests (PETs), see the <code>qr.solve</code> function
<code>turbo</code>	logical. If TRUE, then (parts of) paths are not searched twice (or more) unnecessarily, thus yielding a significant potential for speed-gain. However, the checking of whether the search has arrived at a point it has already been comes with a slight computational overhead. Accordingly, if <code>turbo=TRUE</code> , then the total search time might in fact be higher than if <code>turbo=FALSE</code> . This happens if estimation is very fast, say, less than quarter of a second. Hence the default is FALSE
<code>print.searchinfo</code>	logical. If TRUE (default), then a print is returned whenever simplification along a new path is started
<code>plot</code>	NULL or logical. If TRUE, then the fitted values and the residuals of the final model are plotted after model selection. If FALSE, then they are not. If NULL (default), then the value set by <code>options</code> determines whether a plot is produced or not
<code>alarm</code>	logical. If TRUE, then a sound or beep is emitted (in order to alert the user) when the model selection ends

Details

For an overview, see Pretis, Reade and Sucarrat (2018): <https://www.jstatsoft.org/article/view/v086i03>.

The arguments `user.diagnostics` and `gof.function` enable the specification of user-defined diagnostics and a user-defined goodness-of-fit function. For the former, see the documentation of `diagnostics`. For the latter, the principles of the same arguments in `getsFun` are followed, see its documentation under "Details", and Sucarrat (2019): <https://mpira.ub.uni-muenchen.de/96653/>.

Value

A list of class 'gets'

Author(s)

Genaro Sucarrat, <http://www.sucarrat.net/>

##(20 percent) significance levels:
meanmod04 <- getsm(gum01, t.pval=0.2)

##GETS model selection of log-variance with all the
##log-ARCH terms excluded from removal:
varmod03 <- getsv(gum01, keep=2:4)
```

hpdata *Hoover and Perez (1999) data*

Description

Data used by Hoover and Perez (1999) in their evaluation of General-to-Specific (GETS) modelling. A detailed description of the data is found in their Table 1 (page 172). The data are quarterly, comprise 20 variables (the first variable is the quarterly index) and runs from 1959:1 to 1995:1. This corresponds to 145 observations. The original source of the data is Citibank.

Usage

data(hpdata)

Format

Date a factor that contains the (quarterly) dates of the observations

DCOINC index of four coincident indicators

GD GNP price deflator

GGEQ government purchases of goods and services

GGFEQ federal purchases of goods and services

GGFR federal government receipts

GNPQ GNP

GYDQ disposable personal income

GPIQ gross private domestic investment

FMRRR total member bank reserves

FMBASE monetary base (federal reserve bank of St. Louis)

FM1DQ M1

FM2DQ M2

FSDJ Dow Jones stock price

FYAAAC Moody's AAA corporate bond yield

LHC labour force (16 years+, civilian)

LHUR unemployment rate

MU unfilled orders (manufacturing, all industries)

MO new orders (manufacturing, all industries)

GCQ personal consumption expenditure

Details

The data have been used for comparison and illustration of GETS model selection in several studies of the GETS methodology, including Hendry and Krolzig (1999, 2005), Doornik (2009) and Sucarrat and Escribano (2012).

Examples

```
##load Hoover and Perez (1999) data:
data(hpdata)

##make quarterly data-matrix of zoo type:
newhpdata <- zooreg(hpdata[, -1], start=c(1959,1), frequency=4)

##plot data:
plot(newhpdata)

##transform data to log-differences in percent:
dloghpdata <- diff(log(newhpdata))*100

##plot log-differenced data:
plot(dloghpdata)
```

iim

Make Indicator Matrices (Impulses, Steps, Trends)

Description

Auxiliary functions to make, respectively, matrices of impulse indicators (*iim*), step indicators (*sim*) and trend indicators (*tim*)

Usage

```
##make matrix of impulse indicators:
iim(x, which.ones = NULL)

##make matrix of step indicators:
```

```
sim(x, which.ones = NULL)

##make matrix of trend indicators:
tim(x, which.ones = NULL, log.trend = FALSE)
```

Arguments

x	either an integer (the length of the series in question) or a series (a vector or matrix) from which to use the time-series index to make indicators of
which.ones	the locations of the impulses. If NULL (the default), then all impulses are returned
log.trend	logical. If TRUE, then the natural log is applied on the trends

Details

If x is a series or vector of observations, then the index of x will be used for the labelling of the impulses, and in the returned [zoo](#) object.

Note: For `sim` and `tim` the first indicator is removed, since it is exactly colinear with the others.

Value

A [zoo](#) matrix containing the impulses

Author(s)

Genaro Sucarrat, <http://www.sucarrat.net/>

See Also

[isat](#), [zoo](#)

Examples

```
##generate series:
y <- rnorm(40)

##make matrix of impulse indicators:
mIIM <- iim(40)

##make matrix of step-indicators, but only every third:
mSIM <- sim(y, which.ones=seq(1,40,3))

##give quarterly time-series attributes to y-series:
y <- zooreg(y, frequency=4, end=c(2015,4))

##make matrix of trend-indicators with quarterly labels:
mTIM <- tim(y)
```

infldata	<i>Quarterly Norwegian year-on-year CPI inflation</i>
----------	---

Description

Quarterly Norwegian year-on-year CPI inflation from 1989(1) to 2015(4).

Usage

```
data("infldata")
```

Format

A data frame with 108 observations on the following 5 variables:

date a factor containing the dates

infl year-on-year inflation

q2dum a dummy variable equal to 1 in quarter 2 and 0 otherwise

q3dum a dummy variable equal to 1 in quarter 3 and 0 otherwise

q4dum a dummy variable equal to 1 in quarter 4 and 0 otherwise

Source

Statistics Norway (SSB): <http://www.ssb.no/>. The raw data comprise monthly CPI data obtained via <https://www.ssb.no/statbank/table/08183>.

References

Examples

```
data(infldata)
infldata <- zooreg(infldata[,-1], frequency=4, start=c(1989,1))
plot(infldata[, "infl"])
```

`infocrit`*Computes the Average Value of an Information Criterion*

Description

Given a log-likelihood, the number of observations and the number of estimated parameters, the average value of a chosen information criterion is computed. This facilitates comparison of models that are estimated with a different number of observations, e.g. due to different lags.

Usage

```
infocrit(x, method=c("sc", "aic", "aicc", "hq"))
```

```
info.criterion(logl, n=NULL, k=NULL, method=c("sc", "aic", "aicc", "hq"))
```

Arguments

<code>x</code>	a list that contains, at least, three items: <code>logl</code> (a numeric, the log-likelihood), <code>k</code> (a numeric, usually the number of estimated parameters) and <code>n</code> (a numeric, the number of observations)
<code>method</code>	character, either "sc" (default), "aic", "aicc" or "hq"
<code>logl</code>	numeric, the value of the log-likelihood
<code>n</code>	integer, number of observations
<code>k</code>	integer, number of parameters

Details

Contrary to [AIC](#) and [BIC](#), `info.criterion` computes the average criterion value (i.e. division by the number of observations). This facilitates comparison of models that are estimated with a different number of observations, e.g. due to different lags.

Value

`infocrit`: a numeric (i.e. the value of the chosen information criterion)

`info.criterion`: a list with elements

<code>method</code>	type of information criterion
<code>n</code>	number of observations
<code>k</code>	number of parameters
<code>value</code>	the value on the information criterion

Indicator Saturation

Description

The `isat` function undertakes multi-path indicator saturation to detect outliers and mean-shifts using impulses (IIS), step-shifts (SIS), or trend-indicators (TIS). Indicators are partitioned into blocks and selected over at a chosen level of significance (`t.pval`) using the `getsm` function.

Usage

```
isat(y, mc=TRUE, ar=NULL, ewma=NULL, mxreg=NULL, iis=FALSE, sis=TRUE,
     tis=FALSE, uis=FALSE, blocks=NULL, ratio.threshold=0.8, max.block.size=30,
     t.pval=0.001, wald.pval=t.pval,
     vcov.type= c("ordinary", "white", "newey-west"), do.pet=FALSE, ar.LjungB=NULL,
     arch.LjungB=NULL, normality.JarqueB=NULL, info.method=c("sc", "aic", "hq"),
     user.diagnostics=NULL, user.estimator=NULL, gof.function=NULL,
     gof.method = c("min", "max"), include.gum=NULL, include.1cut=FALSE,
     include.empty=FALSE, max.paths=NULL, parallel.options=NULL, turbo=FALSE,
     tol=1e-07, LAPACK=FALSE, max.regs=NULL, print.searchinfo=TRUE, plot=NULL,
     alarm=FALSE)
```

Arguments

- | | |
|-------------------|--|
| <code>y</code> | numeric vector, time-series or <code>zoo</code> object. Missing values in the beginning and at the end of the series is allowed, as they are removed with the <code>na.trim</code> command |
| <code>mc</code> | logical. TRUE (default) includes an intercept in the mean specification, whereas FALSE does not |
| <code>ar</code> | integer vector, say, <code>c(2,4)</code> or <code>1:4</code> . The AR-lags to include in the mean specification |
| <code>ewma</code> | either NULL (default) or a list with arguments sent to the <code>eqwma</code> function. In the latter case a lagged moving average of <code>y</code> is included as a regressor |

<code>mxreg</code>	numeric vector or matrix, say, a <code>zoo</code> object, of conditioning variables. Note that missing values in the beginning or at the end of the series is allowed, as they are removed with the <code>na.trim</code> command. Note also that, if both <code>y</code> and <code>mxreg</code> are <code>zoo</code> objects, then their samples are chosen to match
<code>iis</code>	logical. If TRUE, impulse indicator saturation is performed.
<code>sis</code>	logical. If TRUE, step indicator saturation is performed.
<code>tis</code>	logical. If TRUE, trend indicator saturation is performed.
<code>uis</code>	a matrix of regressors, or a list of matrices.
<code>blocks</code>	NULL (default), an integer (the number of blocks) or a user-specified list that indicates how blocks should be put together. If NULL, then the number of blocks is determined automatically
<code>ratio.threshold</code>	Minimum ratio of variables in each block to total observations to determine the block size, default=0.8. Only relevant if <code>blocks = NULL</code>
<code>max.block.size</code>	Maximum size of block of variables to be selected over, default=30. Block size used is the maximum of given by either the <code>ratio.threshold</code> and <code>max.block.size</code>
<code>t.pval</code>	numeric value between 0 and 1. The significance level used for the two-sided regressor significance t-tests
<code>wald.pval</code>	numeric value between 0 and 1. The significance level used for the Parsimonious Encompassing Tests (PETs)
<code>vcov.type</code>	the type of variance-covariance matrix used. If NULL (default), then the type used is that of the 'arx' object. This can be overridden by either "ordinary" (i.e. the ordinary variance-covariance matrix) or "white" (i.e. the White (1980) heteroscedasticity robust variance-covariance matrix)
<code>do.pet</code>	logical. If TRUE, then a Parsimonious Encompassing Test (PET) against the GUM is undertaken at each regressor removal for the joint significance of all the deleted regressors along the current path. If FALSE (default), then a PET is not undertaken at each regressor removal. By default, the numeric value is the same as that of <code>t.pval</code>
<code>ar.LjungB</code>	a two-item list with names <code>lag</code> and <code>pval</code> , or NULL (default). In the former case <code>lag</code> contains the order of the Ljung and Box (1979) test for serial correlation in the standardised residuals, and <code>pval</code> contains the significance level. If <code>lag=NULL</code> (default), then the order used is that of the estimated 'arx' object. If <code>ar.Ljungb=NULL</code> , then the standardised residuals are not checked for serial correlation
<code>arch.LjungB</code>	a two-item list with names <code>lag</code> and <code>pval</code> , or NULL (default). In the former case, <code>lag</code> contains the order of the Ljung and Box (1979) test for serial correlation in the squared standardised residuals, and <code>pval</code> contains the significance level. If <code>lag=NULL</code> (default), then the order used is that of the estimated 'arx' object. If <code>arch.Ljungb=NULL</code> , then the standardised residuals are not checked for ARCH
<code>normality.JarqueB</code>	NULL (the default) or a value between 0 and 1. In the latter case, a test for non-normality is conducted using a significance level equal to <code>normality.JarqueB</code> . If NULL, then no test for non-normality is conducted

<code>info.method</code>	character string, "sc" (default), "aic" or "hq", which determines the information criterion to be used when selecting among terminal models. The abbreviations are short for the Schwarz or Bayesian information criterion (sc), the Akaike information criterion (aic) and the Hannan-Quinn (hq) information criterion
<code>user.diagnostics</code>	NULL or a list with two entries, name and pval, see the <code>user.fun</code> argument in diagnostics
<code>user.estimator</code>	NULL or a list with at least one entry, name, see the <code>user.estimator</code> argument in getsFun
<code>gof.function</code>	NULL or a list with at least one entry, name, see the <code>user.estimator</code> argument in getsFun
<code>gof.method</code>	NULL or a character that determines whether the best Goodness-of-Fit is a minimum or maximum
<code>include.gum</code>	ignored (temporarily deprecated)
<code>include.1cut</code>	logical. If TRUE, then the 1-cut model is included among the terminal models, if it passes the diagnostic tests, even if it is not equal to one of the terminals. If FALSE (default), then the 1-cut model is not included (unless it is one of the terminals)
<code>include.empty</code>	logical. If TRUE, then an empty model is included among the terminal models, if it passes the diagnostic tests, even if it is not equal to one of the terminals. If FALSE (default), then the empty model is not included (unless it is one of the terminals)
<code>max.paths</code>	NULL (default) or an integer indicating the maximum number of paths to search
<code>parallel.options</code>	NULL or an integer, i.e. the number of cores/threads to be used for parallel computing (implemented w/makeCluster and parLapply)
<code>turbo</code>	logical. If TRUE, then (parts of) paths are not searched twice (or more) unnecessarily, thus yielding a significant potential for speed-gain. However, the checking of whether the search has arrived at a point it has already been comes with a slight computational overhead. Accordingly, if turbo=TRUE, then the total search time might in fact be higher than if turbo=FALSE. This happens if estimation is very fast, say, less than quarter of a second. Hence the default is FALSE
<code>tol</code>	numeric value (default = 1e-07). The tolerance for detecting linear dependencies in the columns of the regressors (see qr function). Only used if LAPACK is FALSE (default)
<code>LAPACK</code>	logical. If TRUE, then use LAPACK. If FALSE (default), then use LINPACK (see qr function)
<code>max.regs</code>	integer. The maximum number of regressions along a deletion path. It is not recommended that this is altered
<code>print.searchinfo</code>	logical. If TRUE (default), then a print is returned whenever simplification along a new path is started, and whenever regressors are dropped due to exact multicollinearity

plot	NULL or logical. If TRUE, then the fitted values and the residuals of the final model are plotted after model selection. If NULL (default), then the value set by <code>options</code> determines whether a plot is produced or not.
alarm	logical. If TRUE, then a sound is emitted (in order to alert the user) when the model selection ends

Details

Multi-path indicator saturation using impulses (IIS), step-shifts (SIS), or trend-indicators (TIS). Indicators are partitioned into sequential blocks (as of beta version 0.7) where the block intervals are defined by the ratio of variables to observations in each block and a specified maximum block size. Indicators are selected over using the `getsm` function. Retained indicators in each block are combined and re-selected over. Fixed covariates that are not selected over can be included in the regression model either in the `mxreg` matrix, or for auto-regressive terms through the `ar` specification. See Hendry, Johansen and Santos (2007) and Castle, Doornik, Hendry, and Pretis (2015)

Value

A list of class 'gets'

Examples

```
##SIS using the Nile data
data(Nile)
isat(Nile, sis=TRUE, iis=FALSE, plot=TRUE, t.pval=0.005)

##SIS using the Nile data in an autoregressive model
#isat(Nile, ar=1:2, sis=TRUE, iis=FALSE, plot=TRUE, t.pval=0.005)

##HP Data
##load Hoover and Perez (1999) data:
#data(hpdata)

##make quarterly data-matrix of zoo type
##(GCQ = personal consumption expenditure):
#y <- zooreg(hpdata$GCQ, 1959, frequency=4)

##transform data to log-differences:
#dlogy <- diff(log(y))

##run isat with step impulse saturation on four
##lags and a constant 1 percent significance level:
#isat(dlogy, ar=1:4, sis=TRUE, t.pval =0.01)

##Example with additional covariates entering through mxreg:

##(GYDQ = disposable personal income):
#x <- zooreg(hpdata$GYDQ, 1959, frequency=4)

##transform data to log-differences:
#dlogx <- diff(log(x))

##run isat with step impulse saturation on four
##lags and a constant 1 percent significance level:
#isat(dlogy, mxreg=dlogx, ar=1:4, sis=TRUE, t.pval =0.01)
```

isatdates

Extracting Indicator Saturation Breakdates

Description

Takes an `isat` object and extracts the break dates together with their estimated coefficients.

Usage

```
isatdates(x)
```

Arguments

x an `isat` object

Details

The function extracts the breakdates determined by `isat` for `iis`, `sis`, and `tis`, together with their estimated coefficients and standard errors.

Value

Returns a list of three elements (one for `iis`, `sis`, and `tis`). Each element lists the name of the break variable, the time index of the break (labelled 'date'), the index of the break date, the estimated coefficient, the standard error of the estimated coefficient, as well as the corresponding t-statistic and p-value.

`isat`

Examples

```
###Break date extraction of the Nile data
nile <- as.zoo(Nile)
isat.nile <- isat(nile, sis=TRUE, iis=FALSE, plot=TRUE, t.pval=0.005)
isatdates(isat.nile)
```

isatloop

Repeated Impulse Indicator Saturation

Description

Runs `isat` repeatedly at pre-specified significance levels to yield multiple iterations used in `outlierscaletest`.

Usage

```
isatloop(num=c(seq(from=20, to=1, by=-1)), t.pval.spec = FALSE,
print=FALSE, y, ar=NULL, iis=TRUE, sis=FALSE, ...)
```

Arguments

num	numeric, target expected number of outliers under the null hypothesis, or target proportion of outliers if <code>t.pval.spec==TRUE</code>
t.pval.spec	logical, if TRUE, then num specifies proportion rather than number of targeted outliers
print	logical, if TRUE, then iterations are printed
y	numeric vector, time-series or <code>zoo</code> object. Missing values in the beginning and at the end of the series is allowed, as they are removed with the <code>na.trim</code> command
ar	integer vector, say, <code>c(2,4)</code> or <code>1:4</code> . The AR-lags to include in the mean specification
iis	logical, whether to use <code>iis</code>
sis	logical, whether to use <code>sis</code> , default is FALSE
...	any argument from <code>isat</code> can also be used in <code>isatloop</code>

Details

The function repeatedly runs `isat` detecting outliers in a model of `y` at different chosen target levels of significance specified in `num`. The output of this function is used as the input for the `outlierscaletest` function. All additional arguments from `isat` can be passed to `isatloop`.

Value

Returns a list of two items. The first item is the number of observations. The second item is a dataframe containing the expected and observed proportion (and number of outliers) for each specified significance level of selection.

isat.nile.loop <- isatloop(y=nile, iis=TRUE, num=c(1,2, 3, 4, 5))
```

isattest

Indicator Saturation Test

Description

Takes an 'isat' object returned by the `isat` function as input and returns the results of a hypothesis test on the time-varying intercept or long-run equilibrium against a specified null-hypothesis for a chosen level of significance - see Pretis (2015).

Usage

```
isattest(x, hnull=0, lr=FALSE, ci.pval=0.99, plot=NULL, plot.turn=FALSE,
        conscorr=FALSE, effcorr=FALSE, mcor = 1, biascorr=FALSE, mxfull = NULL,
        mxbreak=NULL)
```

Arguments

<code>x</code>	a 'gets' object obtained with the <code>isat</code> function
<code>hnull</code>	numeric. the null-hypothesis value to be tested against.
<code>lr</code>	logical. If TRUE and 'x' contains autoregressive elements, then <code>isattest</code> tests on the long-run equilibrium path. See Pretis (2015).
<code>ci.pval</code>	numeric between 0 and 1. Default is 0.99, the level of significance for the confidence interval of the test against 'hnull'.
<code>plot</code>	logical. If TRUE, then a plot showing the coefficient path and bias relative to 'hnull' is shown.
<code>plot.turn</code>	logical. If TRUE, then the plot output adds the time of the breaks to the plot showing the bias relative to 'hnull'.
<code>biascorr</code>	logical. If TRUE, then the coefficient path is bias-corrected using <code>biascorr</code> . This is only valid for the non-dynamic test without additional covariates.
<code>conscorr</code>	logical. If TRUE then the Johansen and Nielsen (2016) impulse-indicator consistency correction is applied to estimated residual variance.
<code>effcorr</code>	logical. If TRUE then the Johansen and Nielsen (2016) m-step efficiency correction is applied to estimated standard errors of 'fixed' regressors.
<code>mcor</code>	integer. The m-step efficiency correction factor, where $m=mcor$.
<code>mxfull</code>	string. The name of the full-sample variable when constructing the coefficient path of user-specified break variables.
<code>mxbreak</code>	string. The name of the break variables used to construct the coefficient path of user-specified break variables.

Details

The function tests the coefficient path (or long-run equilibrium path) against a specified null hypothesis at a chosen level of significance. If conducted on an `isat` model of a forecast error or relative forecast differential, then this corresponds to the test of time-varying predictive accuracy of Pretis (2015). The resulting output plot shows the coefficient path in the top panel (where `hnull` is plotted as dotted lines), with the bias (significant difference relative to `hnull`) in the lower panel. If `mxfull` and `mxbreak` are specified, then the function tests on the coefficient path of the user-specified variable, where `mxfull` denotes the full-sample variable name, to which the `mxbreak` variables are added. To correct for the under-estimation of the residual variance, the argument `conscorr` implements the Johansen and Nielsen (2016) consistency correction, and `effcorr` adds the efficiency correction for standard errors on fixed regressors which are not selected over.

Value

A $T \times 4$ matrix (with T = number of observations) where the first two columns denote the confidence interval of the coefficient path (or the long-run equilibrium path if `lr=TRUE`). The third and fourth column denote the bias of the coefficient path relative to the chosen null-hypothesis, where `bias.high` denotes the bias when the series tested is above the hypothesized value, and `bias.low` denotes the bias when the series tested is significantly below the hypothesized value.

#y <- d*2 +e
#plot(y, type="l")

##Static Test against hnull=0 using bias-correction:
```

```
#ys <- isat(y, sis=TRUE, iis=FALSE, tis=FALSE, t.pval=0.01)
#isattest(ys, hnull=0, lr=FALSE, ci.pval = 0.99, plot.turn = FALSE, biascorr=TRUE)

##Dynamic Test of the long-run equilibrium against hnull=2 with breakpoints
##labelled in the plot:

#ys <- isat(y, sis=TRUE, iis=FALSE, tis=FALSE, t.pval=0.01, ar=1:2)
#isattest(ys, hnull=2, lr=TRUE, ci.pval = 0.99, plot.turn = TRUE, biascorr=FALSE)
```

isatvar

Variance of the coefficient path

Description

Takes an 'isat' object returned by the `isat` function as input and returns the coefficient path of the constant (and long-run equilibrium if 'lr' is specified) together with its approximate variance and standard errors. If `mxfull` and `mxbreak` are specified, then the function returns the coefficient path of the user-specified variable.

Usage

```
isatvar(x, lr=FALSE, conscorr=FALSE, effcorr=FALSE, mcor = 1,
        mxfull = NULL, mxbreak=NULL)
```

Arguments

<code>x</code>	a 'gets' object obtained with the <code>isat</code> function
<code>lr</code>	logical. If TRUE and 'x' contains autoregressive elements, then <code>isatvar</code> also returns the long-run equilibrium coefficient path with its variance and standard deviation. See Pretis (2015).
<code>conscorr</code>	logical. If TRUE then the Johansen and Nielsen (2016) impulse-indicator consistency correction is applied to estimated residual variance.
<code>effcorr</code>	logical. If TRUE then the Johansen and Nielsen (2016) m-step efficiency correction is applied to estimated standard errors of 'fixed' regressors.
<code>mcor</code>	integer. The m-step efficiency correction factor, where $m=mcor$.
<code>mxfull</code>	string. The name of the full-sample variable when constructing the coefficient path of user-specified break variables.
<code>mxbreak</code>	string. The name of the break variables used to construct the coefficient path of user-specified break variables.

Details

The function computes the approximate variance and standard errors of the intercept term with structural breaks determined by `isat`. This permits hypothesis testing and plotting of approximate confidence intervals for the intercept in the presence of structural breaks. For dynamic autoregressive models in `isat` the `lr` argument returns the time-varying long-run equilibrium together with its approximate variance and standard errors. If `mxfull` and `mxbreak` are specified, then the function returns the coefficient path of the user-specified variable, where `mxfull` denotes the full-sample variable name, to which the `mxbreak` variables are added. To correct for the under-estimation of the residual variance, the argument `conscorr` implements the Johansen and Nielsen (2016) consistency correction, and `effcorr` adds the efficiency correction for standard errors on fixed regressors which are not selected over.

Value

If `lr=FALSE`: A $T \times 4$ matrix (with T = number of observations) where the first column denotes the coefficient path relative to the full sample coefficient, the second column the coefficient path of the intercept, the third the approximate variance of the coefficient path, and the fourth column the approximate standard errors of the coefficient path. If `lr=TRUE`: A $T \times 7$ matrix where the first four columns are identical to the `lr=FALSE` case, and the additional columns denote the long-run equilibrium coefficient path, together with the approximate variance and standard errors of the long-run equilibrium coefficient path.

```

isatvarcorrect	<i>Consistency and Efficiency Correction for Impulse Indicator Saturation</i>
----------------	---

Description

Takes an `isat` object and corrects the estimates of the error variance and the estimated standard errors of 'forced' regressors.

Usage

```
isatvarcorrect(x, mcor=1)
```

Arguments

<code>x</code>	an <code>isat</code> object
<code>mcor</code>	integer, number of iterations in the correction. Default = 1.

Details

Impulse indicator saturation results in an under-estimation of the error variance as well as the variance of regressors not selected over. The magnitude of the inconsistency increases with the p-value of selection (`t.pval`). The function takes an `isat` object and applies the impulse indicator consistency (`isvarcor`) and efficiency correction (`isvareffcor`) of the estimated error variance and the estimated variance of regressors not selected over. See Johansen and Nielsen (2016a) and (2016b).

Value

Returns an `isat` object in which the estimated standard errors, t-statistics, p-values, standard error of the regression, and log-likelihood are consistency and efficiency corrected when using impulse indicator saturation (`iis=TRUE`).

isvarcor

IIS Consistency Correction

Description

Consistency correction for estimate of residual variance when using impulse indicator saturation.

Usage

```
isvarcor(t.pval, sigma)
```

Arguments

t.pval	numeric value. the p-value of selection in the impulse indicator saturation model.
sigma	numeric value. The estimated standard deviation of the residuals from the impulse indicator saturation model.

Details

The Johansen and Nielsen (2016) impulse-indicator consistency correction for the estimated residual standard deviation.

Value

a data frame containing the corrected standard deviation `$sigma.cor` and the correction factor used `$corxi`

isvareffcor

IIS Efficiency Correction

Description

Efficiency correction for the estimates of coefficient standard errors on fixed regressors.

Usage

```
isvareffcor(t.pval, se, m=1)
```

Arguments

t.pval	numeric value. the p-value of selection in the impulse indicator saturation model.
se	numeric value or vector. The estimated standard errors of the coefficients on fixed regressors in impulse indicator saturation model.
m	integer. The m-step correction factor.

Details

The Johansen and Nielsen (2016) impulse-indicator efficiency correction for the estimated standard errors on fixed regressors in impulse indicator models.

Value

a data frame containing the corrected standard deviation `$se.cor` and the correction factor used `$eta.m`

mvrnormsim

Simulate from a Multivariate Normal Distribution

Description

Produces one or more samples from the specified multivariate normal distribution. Used in [outlierscaletest](#).

Usage

```
mvrnormsim(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE)
```

Arguments

n	the number of samples required.
mu	a vector giving the means of the variables.
Sigma	a positive-definite symmetric matrix specifying the covariance matrix of the variables.
tol	tolerance (relative to largest variance) for numerical lack of positive-definiteness in Sigma.
empirical	logical. If true, mu and Sigma specify the empirical not population mean and covariance matrix.

Details

Original function `mvrnorm` developed by Venables, W. N. & Ripley. in package MASS, <https://CRAN.R-project.org/package=MASS>.

Value

If $n = 1$ a vector of the same length as `mu`, otherwise an n by `length(mu)` matrix with one sample in each row.

ols *OLS estimation*

Description

OLS estimation with the QR decomposition and, for some options, computation of variance-covariance matrices

Usage

```
ols(y, x, untransformed.residuals=NULL, tol=1e-07, LAPACK=FALSE, method=3,
    variance.spec=NULL, ...)
```

Arguments

y	numeric vector, the regressand
x	numeric matrix, the regressors
untransformed.residuals	NULL (default) or, when <code>ols</code> is used with <code>method=6</code> , a numeric vector containing the untransformed residuals
tol	numeric value. The tolerance for detecting linear dependencies in the columns of the regressors, see the <code>qr</code> function. Only used if LAPACK is FALSE
LAPACK	logical, TRUE or FALSE (default). If true use LAPACK otherwise use LINPACK, see the <code>qr</code> function
method	an integer, 1 to 6, that determines the estimation method
variance.spec	NULL or a list with items that specifies the log-variance model to be estimated, see arx
...	further arguments (currently ignored)

Details

`method = 1` or `method = 2` only returns the OLS coefficient estimates together with the QR-information, the former being slightly faster. `method=3` returns, in addition, the ordinary variance-covariance matrix of the OLS estimator. `method=4` returns the White (1980) heteroscedasticity robust variance-covariance matrix in addition to the information returned by `method=3`, whereas `method=5` does the same except that the variance-covariance matrix now is that of Newey and West (1987). `method=6` undertakes OLS estimation of a log-variance model, see Pretis, Reade and Scurrat (2018, Section 4). Alternatively, for `method 1` to `5`, a log-variance model is also estimated if `variance.spec` is not NULL.

Value

A list with items depending on `method`

outlierscaletest

Sum and Sup Scaling Outlier Tests

Description

Computes the Sum and Supremum Scaling Tests for the overall presence of outliers based on Jiao and Pretis (2019).

Usage

```
outlierscaletest(x, nsim = 10000)
```

Arguments

x	list, output of the isatloop function
nsim	integer, number of replications to simulate critical values for the Sup test

Details

The function takes the output of the [isatloop](#) function and computes the Scaling Sum and Supremum Tests for the presence of outliers from Jiao and Pretis (2019). The test compares the expected and observed proportion of outliers over the range of different significance levels of selection specified in [isatloop](#). The Sum test compares the sum of deviations against the standard normal distribution, the Sup test compares the supremum of deviations against critical values simulated with `nsim` replications. The null hypothesis is that the observed proportion of outliers scales with the proportion of outliers under the null of no outliers.

Value

Returns a list of two `htest` objects. The first providing the results of the Sum test on the sum of the deviation of outliers against a standard normal distribution. The second providing the results on the supremum of the deviation of outliers against simulated critical values.

Author(s)

Xiyu Jiao, & Felix Pretis, <http://www.felixpretis.org/>

Examples

```
###Repeated isat models using the Nile dataset
### where p-values are chosen such that the expected number of outliers under the null
### corresponds to 1, 2, ..., 20. Then computing the Outlier Scaling Tests:

#nile <- as.zoo(Nile)
#isat.nile.loop <- isatloop(y=nile)
#outlierscaletest(isat.nile.loop)
```

outliertest

Jiao and Pretis Outlier Proportion and Count Tests

Description

Tests whether the proportion (or number) of outliers detected using impulse indicator saturation is different from the proportion (or number) of outliers expected under the null hypothesis of no outliers using the Jiao and Pretis (2019) proportion and count outlier tests.

Usage

```
outliertest(x, noutl=NULL, t.pval=NULL, T=NULL,
m=1, infty=FALSE, alternative="two.sided")
```

Arguments

x	an <code>isat</code> object
nout1	integer, number of detected outliers if no <code>isat</code> object is provided i.e. x=NULL
t.pval	numeric, between 0 and 1. Selection p-value used in indicator saturation if no <code>isat</code> object is provided i.e. x=NULL
T	integer, sample sized used in indicator saturation if no <code>isat</code> object is provided i.e. x=NULL
m	integer, number of iterations in variance computation, default=1
infty	logical, argument used for variance computation
alternative	"two-sided", "less", "greater", alternative hypothesis of outlier test.

Details

The function computes the estimated proportion of outliers (gauge) based on impulse indicator saturation and constructs the proportion and count outlier test statistics from Jiao and Pretis (2019). The null hypothesis is that the proportion (or count) of outliers is not different than the proportion (or count) of outliers detected under the null hypothesis of no outliers. The first test compares the estimated proportion of outliers scaled by its estimated variance against a standard normal distribution. The second test compares the number of outliers against a Poisson distribution. If an `isat` object is provided in x, then the function automatically extracts the detected impulses and computes the estimated outlier proportion. If no `isat` object is provided and x=NULL, then the tests can be conducted manually by providing the number of detected outliers (nout1), the sample size (T), and the chosen level of significance used to detect outliers (t.pval).

Value

Returns a list of two `htest` objects. The first providing the results of the test on the proportion of outliers against a standard normal distribution. The second providing the results on the number of outliers against the Poisson distribution.

paths

*Extraction functions for 'arx', 'gets' and 'isat' objects***Description**

Extraction functions for objects of class 'arx', 'gets' and 'isat'

Usage

```

paths(object, ...)
terminals(object, ...)
rsquared(object, adjusted=FALSE, ...)

```

Arguments

object	an object of class 'arx', 'gets' or 'isat'
adjusted	logical. If TRUE the adjusted R-squared is returned
...	additional arguments

Details

paths and terminals can only be applied on objects of class 'gets' and 'isat'

Value

paths:	a list with the paths searched (each number refers to a regressor in the GUM)
terminals:	a list with the terminal models (each number refers to a regressor in the GUM)
rsquared:	a numeric , the R-squared of the regression, or adjusted R-squared if adjusted is set to TRUE

periodicdummies

Make matrix of periodicity (e.g. seasonal) dummies

Description

Auxiliary function that generates periodicity dummies (e.g. seasonal dummies) for regular time series. The function is similar to, but more general than, the `seasonaldummy` function in the `forecast` package.

Usage

```
periodicdummies(x, values=1)
```

Arguments

x	a regular time series (vector or matrix)
values	numeric of length 1 (default) or numeric vector of length equal to frequency(x)

Value

A matrix of class `zoo` with the periodicity dummies

Author(s)

Genaro Sucarrat, <http://www.sucarrat.net/>

See Also

##monthly dummies:
y <- zooreg(rnorm(30), start=c(2000,1), frequency=12)
periodicdummies(y)
```

predict.arx

Forecasting with 'arx' models

Description

Generate out-of-sample forecasts up to `n` steps ahead for objects of class `arx`. Optionally, quantiles of the forecasts are also returned if any of the arguments `ci.levels` or `probs` are specified. The forecasts, confidence intervals and quantiles are obtained via simulation. By default, 5000 simulations is used, but this can be changed via the `n.sim` argument. Also by default, the simulations uses a classical bootstrap to sample from the standardised residuals. To use an alternative set of standardised innovations, for example the standard normal, use the `innov` argument. If `plot=TRUE`, then a plot of the forecasts is created.

Usage

```
## S3 method for class 'arx'
predict(object, spec=NULL, n.ahead=12, newmxreg=NULL,
        newvxreg=NULL, newindex=NULL, n.sim=5000, innov=NULL, probs=NULL,
        ci.levels=NULL, quantile.type=7, return=TRUE, verbose=FALSE,
        plot=NULL, plot.options=list(), ...)
```

Arguments

<code>object</code>	an object of class 'arx'
<code>spec</code>	NULL (default), "mean", "variance" or "both". If NULL, then it is automatically determined whether information pertaining to the mean or variance specification should be returned
<code>n.ahead</code>	integer that determines how many steps ahead predictions should be generated (the default is 12)

newmxreg	a matrix of <code>n.ahead</code> rows and <code>NCOL(mxreg)</code> columns with the out-of-sample values of the <code>mxreg</code> regressors
newvxreg	a matrix of <code>n.ahead</code> rows and <code>NCOL(vxreg)</code> columns with the out-of-sample values of the <code>vxreg</code> regressors
newindex	NULL (default) or the date-index for the zoo object returned by <code>predict.arx</code> . If NULL, then the function uses the in-sample index to generate the out-of-sample index
n.sim	integer, the number of replications used for the generation of the forecasts
innov	NULL (default) or a vector of length <code>n.ahead * n.sim</code> containing the standardised errors (that is, zero mean and unit variance) used for the forecast simulations. If NULL, then a classical bootstrap procedure is used to draw from the standardised in-sample residuals
probs	NULL (default) or a vector with the quantile-levels (values strictly between 0 and 1) of the forecast distribution. If NULL, then no quantiles are returned unless <code>ci.levels</code> is non-NULL
ci.levels	NULL (default) or a vector with the confidence levels (expressed as values strictly between 0 and 1) of the forecast distribution. The upper and lower values of the confidence interval(s) are returned as quantiles
quantile.type	an integer between 1 and 9 that selects which algorithm to be used in computing the quantiles, see the argument <code>type</code> in quantile
return	logical. If TRUE (default), then the out-of-sample predictions are returned. The value FALSE, which does not return the predictions, may be of interest if only a prediction plot is of interest
verbose	logical with default FALSE. If TRUE, then additional information (typically the quantiles and/or the simulated series) used in the generation of forecasts is returned. If FALSE, then only the forecasts are returned
plot	NULL (default) or logical. If NULL, then the value set by <code>options\$plot</code> (see options) determines whether a plot is produced or not. If TRUE, then the out-of-sample forecasts are plotted.
plot.options	a list of options related to the plotting of forecasts, see 'Details'
...	additional arguments

Details

The `plot.options` argument is a list that, optionally, can contain any of the following arguments:

- `keep`: integer greater than zero (the default is 12) that controls the number of in-sample actual values to plot
- `line.at.origin`: logical. If TRUE, then a vertical line is drawn at the forecast origin, that is, at the last in-sample observation
- `start.at.origin`: logical. If TRUE, then the drawing of the forecast line starts at the actual value of the forecast origin

- `dot.at.origin`: logical. If TRUE, then a dot is drawn at the forecast origin
- `hlines`: numeric vector that indicates where to draw grey horizontal grid lines
- `col`: numeric vector of length two that controls the colour of the plotted lines. The first value controls the colour of the forecasts and the fitted values, whereas the second controls the colour of the actual values
- `lty`: numeric vector of length two that controls the line type. The first value controls the line type of the forecast, whereas the second controls the line type of the actual and fitted values
- `lwd`: an integer that controls the width of the plotted lines (the default is 1)
- `ylim`: numeric vector of length two that contains the limits of the y-axis of the prediction plot
- `ylab`: a character that controls the text on the y-axis
- `main`: a character that controls the text in the overall title
- `legend.text`: a character vector of length two that controls how the forecast and actual lines should be named or referred to in the legend of the plot
- `fitted`: If TRUE, then the fitted values as well as actual values are plotted in-sample
- `newmactual`: numeric vector or NULL (default). Enables the plotting of actual values out-of-sample in the mean in addition to the forecasts
- `newvactual`: numeric vector or NULL (default). Enables the plotting of squared residuals ('actual values') out-of-sample in addition to the forecasts
- `shades`: numeric vector of length `length(ci.levels)` that contains the shades of grey associated with the confidence intervals in the prediction plot. The shades can range from 100 (white) to 0 (black)

Value

a vector of class `zoo` containing the out-of-sample forecasts, or a matrix of class `zoo` containing the out-of-sample forecasts together with prediction-quantiles, or NULL if `return=FALSE`

Author(s)

Felix Pretis, <http://www.felixpretis.org/>
James Reade, <https://sites.google.com/site/jjamesreade/>

```

##simulate from an AR(1):
set.seed(123)
y <- arima.sim(list(ar=0.4), 40)

##estimate AR(2) model with intercept:
mymod <- arx(y, mc=TRUE, ar=c(1,2))

##generate out-of-sample forecasts:
predict(mymod)

##same, but plot the predictions in addition:
#predict(mymod, plot=TRUE)

##same, but return also the quantiles of the confidence intervals:
#predict(mymod, ci.levels=c(0.50,0.90), plot=TRUE)

##same, but with non-default levels on the confidence intervals:
#predict(mymod, ci.levels=c(0.20,0.80, 0.99), plot=TRUE)

##same, but with more confidence intervals:
#predict(mymod, ci.levels=seq(0.20, 0.95, by=0.05), plot=TRUE)

##same, but with less rugged ci's (achieved by increasing n.sim):
##predict(mymod, ci.levels=seq(0.20, 0.95, by=0.05), n.sim=50000, plot=TRUE)

##same, but using standard normals (instead of bootstrap) in the simulations:
#n.sim <- 2000
#n.ahead <- 12 #the default on n.ahead
#predict(mymod, ci.levels=seq(0.20, 0.95, by=0.05), n.sim=n.sim,
# innov=rnorm(n.ahead*n.sim), plot=TRUE)

##make x-regressors:
x <- matrix(rnorm(40*3), 40, 3)

##estimate AR(1) model with intercept and covariates:
mymod <- arx(y, mc=TRUE, ar=1, mxreg=x)

##predict up to 5 steps ahead, setting x's to 0 out-of-sample:
predict(mymod, n.ahead=5, newmxreg=matrix(0,5,NCOL(x)))

##same, but do also plot:
#predict(mymod, n.ahead=5, newmxreg=matrix(0,5,NCOL(x)),
# plot=TRUE)

##estimate an AR(2) model w/intercept and a log-ARCH(1) specification
##on the variance:
#mymodel <- arx(y, mc=TRUE, ar=1:2, arch=1)

```

```

##generate forecasts of the conditional variances:
#predict(mymodel, spec="variance")

##same, but do also plot:
#predict(mymodel, spec="variance", plot=TRUE)

##illustrations of the usage of plot.options:
#mymodel <- arx(y, mc=TRUE, ar=1)
#predict(mymodel, plot=TRUE, plot.options=list(keep=1))
#predict(mymodel, plot=TRUE, plot.options=list(line.at.origin=TRUE))
#predict(mymodel, plot=TRUE, plot.options=list(start.at.origin=FALSE))
#predict(mymodel, plot=TRUE,
# plot.options=list(start.at.origin=FALSE, fitted=TRUE))

#predict(mymodel, plot=TRUE, plot.options=list(ylab="User-specified y-axis"))
#predict(mymodel, plot=TRUE,
# plot.options=list(main="User-specified overall title"))
#predict(mymodel, plot=TRUE,
# plot.options=list(legend.text=c("User-specified 1","User-specified 2")))
#predict(mymodel, plot=TRUE, plot.options=list(fitted=TRUE))
#predict(mymodel, plot=TRUE, plot.options=list(newmactual=rep(0,6)))
#predict(mymodel, plot=TRUE, plot.options=list(shades.of.grey=c(95,50)))
#predict(mymodel, plot=TRUE, plot.options=list(shades.of.grey=c(50,95))) #invert shades

```

printtex

Generate LaTeX code of an estimation result

Description

Convenience functions that generates LaTeX-code of an estimation result in equation-form. `printtex` can, in principle, be applied to any object for which `coef`, `vcov` and `logLik` methods exist. Note: The generated LaTeX-code contains an `eqnarray` environment, which requires that the `amsmath` package is loaded in the preamble of the LaTeX document.

Usage

```

printtex(x, fitted.name=NULL, xreg.names=NULL, digits=4,
         intercept=TRUE, gof=TRUE, diagnostics=TRUE, nonumber=FALSE,
         nobs="T")
## S3 method for class 'arx'
toLatex(object, ...)
## S3 method for class 'gets'
toLatex(object, ...)

```

Arguments

<code>x</code>	an estimation result, e.g. <code>arx</code> , <code>gets</code> or <code>isat</code> object
<code>object</code>	an estimation result of class <code>arx</code> or <code>gets</code>
<code>fitted.name</code>	NULL or a user-specified name of left-hand side variable
<code>xreg.names</code>	NULL or a user-specified character vector with the names of regressors
<code>digits</code>	integer, the number of digits to be printed
<code>intercept</code>	logical or numeric. The argument determines whether one of the regressors is an intercept or not, or its location. If TRUE, then the intercept is assumed to be located at <code>coef(x)[1]</code> , and hence the regressor-name of location 1 is excluded from the print. If FALSE, then it is assumed that there is no intercept among the regressors. If numeric, then it is assumed that the regressors contain an intercept at the location equal to the numeric value
<code>gof</code>	logical, whether to include goodness-of-fit in the print
<code>diagnostics</code>	logical, whether to include diagnostics in the print
<code>nonumber</code>	logical, whether to remove or not (default) the equation-numbering
<code>nobs</code>	character, the notation to use to denote the number of observations
<code>...</code>	arguments passed on to <code>printtex</code>

Details

Currently, `toLatex.arx` and `toLatex.gets` are simply wrappers to `printtex`

Value

LaTeX code of an estimation result

Author(s)

Genaro Sucarrat, <http://www.sucarrat.net/>

See Also

[arx](#), [getsm](#), [getsv](#), [isat](#)

Examples

```
##simulate random variates, estimate model:
y <- rnorm(30)
mX <- matrix(rnorm(30*2), 30, 2)
mymod <- arx(y, mc=TRUE, ar=1:3, mxreg=mX)

##print latex code of estimation result:
printtex(mymod)

##add intercept, at the end, to regressor matrix:
mX <- cbind(mX,1)
colnames(mX) <- c("xreg1", "xreg2", "intercept")
```

```

mymod <- arx(y, mxreg=mX)

##set intercept location to 3:
printtex(mymod, intercept=3)

```

recursive	<i>Recursive estimation</i>
-----------	-----------------------------

Description

Recursive estimation of coefficients and standard errors

Usage

```

recursive(object, spec="mean", std.errors=TRUE, from=40, tol=1e-07,
  LAPACK=FALSE, plot=TRUE, return=TRUE)

```

Arguments

object	an arx , gets or isat object
spec	'mean' or 'variance'. If 'mean' (default), the the recursive estimates of the mean-equation are estimated
std.errors	logical. If TRUE (default), then the coefficient standard errors are also computed
from	integer. The starting point of the recursion
tol	numeric. The tolerance for linear dependency among regressors
LAPACK	logical, TRUE or FALSE (default). If true use LAPACK otherwise use LINPACK, see qr function
plot	NULL or logical. If TRUE, then the recursive coefficient estimates are plotted. If NULL (default), then the value set by options determines whether a plot is produced or not.
return	logical. If TRUE (default), then the recursive estimates are returned in a list

Value

If return=TRUE, then a [list](#) is returned with the following components:

estimates	a zoo matrix with the recursive estimates
standard.errors	a zoo matrix with the standard errors

Author(s)

Genaro Sucarrat, <http://www.sucarrat.net/>

See Also

[ols](#), [qr](#), [solve.qr](#)

Examples

```
##generate random variates, estimate model:
y <- rnorm(100)
mX <- matrix(rnorm(4*100), 100, 4)
mymodel <- arx(y, mc=TRUE, mxreg=mX)

##compute recursive estimates and plot them:
recursive(mymodel)
```

regressorsMean	<i>Create the regressors of the mean equation</i>
----------------	---

Description

The function generates the regressors of the mean equation in an [arx](#) model. The returned value is a matrix with the regressors and, by default, the regressand in column one. By default, observations (rows) with missing values are removed in the beginning and the end with [na.trim](#), and the returned matrix is a [zoo](#) object.

Usage

```
regressorsMean(y, mc = FALSE, ar = NULL, ewma = NULL, mxreg = NULL,
  return.regressand = TRUE, return.as.zoo = TRUE, na.trim = TRUE,
  na.omit=FALSE)
```

Arguments

<code>y</code>	numeric vector, time-series or zoo object.
<code>mc</code>	logical. TRUE includes an intercept, whereas FALSE (default) does not.
<code>ar</code>	either NULL (default) or an integer vector, say, <code>c(2, 4)</code> or <code>1:4</code> with the AR-lags to include in the mean specification. If NULL, then no lags are included.
<code>ewma</code>	either NULL (default) or a list with arguments sent to the eqwma function. In the latter case a lagged moving average of <code>y</code> is included as a regressor.
<code>mxreg</code>	either NULL (default), numeric vector or matrix, say, a zoo object, or data.frame containing conditioning variables (covariates). Note that, if both <code>y</code> and <code>mxreg</code> are zoo objects, then their samples are matched.
<code>return.regressand</code>	logical. TRUE, the default, includes the regressand as column one in the returned matrix.
<code>return.as.zoo</code>	TRUE, the default, returns the matrix as a zoo object.
<code>na.trim</code>	TRUE, the default, removes observations with NA-values in the beginning and the end with na.trim .
<code>na.omit</code>	TRUE, the non-default, removes observations with NA-values, not necessarily in the beginning or in the end, with na.omit .

Value

A matrix, by default of class `zoo`, with the regressand as column one (the default).

Examples

```
##generate some data:
y <- rnorm(10) #regressand
x <- matrix(rnorm(10*5), 10, 5) #regressors

##create regressors (examples):
regressorsMean(y, mxreg=x)
regressorsMean(y, mxreg=x, return.regressand=FALSE)
regressorsMean(y, mc=TRUE, ar=1:3, mxreg=x)
regressorsMean(log(y^2), mc=TRUE, ar=c(2,4))

##let y and x be time-series:
y <- ts(y, frequency=4, end=c(2018,4))
x <- ts(x, frequency=4, end=c(2018,4))
regressorsMean(y, mxreg=x)
regressorsMean(y, mc=TRUE, ar=1:3, mxreg=x)
regressorsMean(log(y^2), mc=TRUE, ar=c(2,4))

##missing values (NA):
y[1] <- NA
x[10,3] <- NA
regressorsMean(y, mxreg=x)
regressorsMean(y, mxreg=x, na.trim=FALSE)
```

regressorsVariance *Create the regressors of the variance equation*

Description

The function generates the regressors of the log-variance equation in an [arx](#) model. The returned value is a matrix with the regressors and, by default, the regressand in column one. By default, observations (rows) with missing values are removed in the beginning and the end with [na.trim](#), and the returned matrix is a [zoo](#) object.

Usage

```
regressorsVariance(e, vc = TRUE, arch = NULL, asym = NULL,
  log.ewma = NULL, vxreg = NULL, zero.adj = 0.1, vc.adj = TRUE,
  return.regressand = TRUE, return.as.zoo = TRUE, na.trim = TRUE,
  na.omit = FALSE)
```

Arguments

e	numeric vector, time-series or zoo object.
vc	logical. TRUE includes an intercept in the log-variance specification, whereas FALSE (default) does not. If the log-variance specification contains any other item but the log-variance intercept, then vc is set to TRUE
arch	either NULL (default) or an integer vector, say, c(1,3) or 2:5. The log-ARCH lags to include in the log-variance specification
asym	either NULL (default) or an integer vector, say, c(1) or 1:3. The asymmetry (i.e. 'leverage') terms to include in the log-variance specification
log.ewma	either NULL (default) or a vector of the lengths of the volatility proxies, see leqmma
vxreg	either NULL (default) or a numeric vector or matrix, say, a zoo object, of conditioning variables. If both y and mxreg are zoo objects, then their samples are chosen to match
zero.adj	numeric value between 0 and 1. The quantile adjustment for zero values. The default 0.1 means the zero residuals are replaced by the 10 percent quantile of the absolute residuals before taking the logarithm
vc.adj	logical. If TRUE (default), then the log-variance intercept is adjusted by the estimate of $E[\ln(z^2)]$, where z is the standardised error. This adjustment is needed for the conditional scale to be equal to the conditional standard deviation. If FALSE, then the log-variance intercept is not adjusted
return.regressand	logical. TRUE, the default, includes the regressand as column one in the returned matrix.
return.as.zoo	TRUE, the default, returns the matrix as a zoo object.

<code>na.trim</code>	TRUE, the default, removes observations with NA-values in the beginning and the end with <code>na.trim</code> .
<code>na.omit</code>	TRUE, the non-default, removes observations with NA-values, not necessarily in the beginning or in the end, with <code>na.omit</code> .

Value

A matrix, by default of class `zoo`, with the regressand as column one (the default).

```

so2data

UK SO2 Data

Description

UK Annual Total Anthropogenic Sulphur Dioxide (SO₂) Emissions 1946-2005.

Usage

```
data("so2data")
```

Format

A data frame with 60 observations on the following 4 variables.

year Year of observation

uk_tot_so2 UK annual total anthropogenic SO₂ emissions in gigagrams

Luk_tot_so2 Log of UK annual total anthropogenic SO₂ emissions

DLuk_tot_so2 First difference of Log UK annual total anthropogenic SO₂ emissions

Details

Data reports the total estimated anthropogenic SO₂ emissions aggregated over coal, petroleum, biomass combustion, smelting, fuel processing, and other processes.

data(so2data)

##create annual zoo object:
newso2data<- zooreg(so2data[,-1], start=1946, frequency=1)

##plot UK annual total anthropogenic SO2 emissions:
plot(newso2data$uk_tot_so2)
```

sp500data

Daily Standard and Poor's 500 index data

Description

Daily Standard and Poor's 500 (SP500) index data from 3 January 1950 to 8 March 2016.

Usage

```
data("sp500data")
```

Format

A data frame with 16652 observations on the following 7 variables:

Date the dates

Open the opening values of the index

High the daily maximum value of the index

Low the daily minimum value of the index

Close the closing values of the index

Volume the traded volume

Adj.Close the adjusted closing values of the index

```

`vargaugeiis`*Variance of the Impulse Indicator Saturation Gauge*

Description

Computes the variance of the gauge (false-positive rate of outliers under the null of no outliers) in impulse indicator saturation based on Jiao and Pretis (2019).

Usage

```
vargaugeiis(t.pval, T, infty=FALSE, m=1)
```

Arguments

<code>t.pval</code>	numeric, between 0 and 1. Selection p-value used in indicator saturation.
<code>T</code>	integer, sample sized used in indicator saturation.
<code>m</code>	integer, number of iterations in variance computation, default=1
<code>infty</code>	logical, argument used for variance computation

Details

The function computes the variance of the Gauge (false-positive rate of outliers in impulse indicator saturation) for a given level of significance of selection (`t.pval`) and sample size (`T`) based on Jiao and Pretis (2019). This is an auxilliary function used within the `outliertest` function.

Value

Returns a dataframe of the variance and standard deviation of the gauge, as well the asymptotic variance and standard deviation.
