

# Package ‘magrittr’

August 29, 2016

**Type** Package

**Title** A Forward-Pipe Operator for R

**Version** 1.5

**Author** Stefan Milton Bache <stefan@stefanbache.dk> and  
Hadley Wickham <h.wickham@gmail.com>

**Maintainer** Stefan Milton Bache <stefan@stefanbache.dk>

**Description** Provides a mechanism for chaining commands with a  
new forward-pipe operator, `%>%`. This operator will forward a  
value, or the result of an expression, into the next function  
call/expression. There is flexible support for the type  
of right-hand side expressions. For more information, see  
package vignette.

To quote Rene Magritte, “Ceci n'est pas un pipe.”

**Suggests** testthat, knitr

**VignetteBuilder** knitr

**License** MIT + file LICENSE

**ByteCompile** Yes

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2014-11-22 19:15:57

<b>Index</b>	<b>12</b>
--------------	-----------

---

debug_fseq	<i>Debugging function for functional sequences.</i>
------------	---

---

### Description

This is a utility function for marking functions in a functional sequence for debugging.

### Usage

```
debug_fseq(fseq, ...)
```

```
undebug_fseq(fseq)
```

### Arguments

fseq	a functional sequence.
...	indices of functions to debug.

### Value

invisible(NULL).

---

debug_pipe	<i>Debugging function for magrittr pipelines.</i>
------------	---

---

### Description

This function is a wrapper around browser, which makes it easier to debug at certain places in a magrittr pipe chain.

### Usage

```
debug_pipe(x)
```

### Arguments

x	a value
---	---------

### Value

x

---

extract	<i>Aliases</i>
---------	----------------

---

### Description

magrittr provides a series of aliases which can be more pleasant to use when composing chains using the %>% operator.

### Details

Currently implemented aliases are

extract	'['
extract2	'[['
inset	'[<-'
inset2	'[[<-'
use_series	('\$'
add	'+'
subtract	'-'
multiply_by	'*'
raise_to_power	'^'
multiply_by_matrix	'**'
divide_by	'/'
divide_by_int	'/%'
mod	'%%'
is_in	'%in%'
and	'&'
or	' '
equals	'=='
is_greater_than	'>'
is_weakly_greater_than	'>='
is_less_than	'<'
is_weakly_less_than	'<='
not('n'est pas')	'!'
set_colnames	'colnames<-'
set_rownames	'rownames<-'
set_names	'names<-'

### Examples

```
iris %>%
  extract(, 1:4) %>%
  head
```

```
good.times <-
  Sys.Date() %>%
  as.POSIXct %>%
```

```

seq(by = "15 mins", length.out = 100) %>%
data.frame(timestamp = .)

good.times$quarter <-
good.times %>%
use_series(timestamp) %>%
format("%M") %>%
as.numeric %>%
divide_by_int(15) %>%
add(1)

```

---

freduce	<i>Apply a list of functions sequentially</i>
---------	---

---

### Description

This function applies the first function to value, then the next function to the result of the previous function call, etc.

### Usage

```
freduce(value, function_list)
```

### Arguments

value            initial value.  
function\_list   a list of functions.

### Value

The result after applying each function in turn.

---

functions	<i>Extract the function list from a functional sequence.</i>
-----------	--

---

### Description

This can be used to extract the list of functions inside a functional sequence created with a chain like . %>% foo %>% bar.

### Usage

```
functions(fseq)
```

### Arguments

fseq            A functional sequence ala magrittr.

**Value**

a list of functions

---

magrittr *magrittr - Ceci n'est pas un pipe*

---

**Description**

The magrittr package offers a set of operators which promote semantics that will improve your code by

- structuring sequences of data operations left-to-right (as opposed to from the inside and out),
- avoiding nested function calls,
- minimizing the need for local variables and function definitions, and
- making it easy to add steps anywhere in the sequence of operations.

The operators pipe their left-hand side values forward into expressions that appear on the right-hand side, i.e. one can replace  $f(x)$  with  $x \%>\% f$ , where  $\%>\%$  is the (main) pipe-operator.

Consider the example below. Four operations are performed to arrive at the desired data set, and they are written in a natural order: the same as the order of execution. Also, no temporary variables are needed. If yet another operation is required, it is straight-forward to add to the sequence of operations wherever it may be needed.

For a more detailed introduction see the vignette (`vignette("magrittr")`) or the documentation pages for the available operators:

<code>\%&gt;\%</code>	forward-pipe operator.
<code>\%T&gt;\%</code>	tee operator.
<code>\%&lt;&gt;\%</code>	compound assignment pipe-operator.
<code>\%\$\%</code>	exposition pipe-operator.

**Examples**

```
## Not run:  
  
the_data <-  
  read.csv('/path/to/data/file.csv') \%>\%  
  subset(variable_a > x) \%>\%  
  transform(variable_c = variable_a/variable_b) \%>\%  
  head(100)  
  
## End(Not run)
```

---

<code>print.fseq</code>	<i>Print method for functional sequence.</i>
-------------------------	--

---

**Description**

Print method for functional sequence.

**Usage**

```
## S3 method for class 'fseq'
print(x, ...)
```

**Arguments**

<code>x</code>	A functional sequence object
<code>...</code>	not used.

**Value**

`x`

---

<code>[[.fseq</code>	<i>Extract function(s) from a functional sequence.</i>
----------------------	--

---

**Description**

Functional sequences can be subset using single or double brackets. A single-bracket subset results in a new functional sequence, and a double-bracket subset results in a single function.

**Usage**

```
## S3 method for class 'fseq'
x[[...]]

## S3 method for class 'fseq'
x[...]
```

**Arguments**

<code>x</code>	A functional sequence
<code>...</code>	index/indices. For double brackets, the index must be of length 1.

**Value**

A function or functional sequence.

**Description**

Pipe an object forward into a function or call expression and update the lhs object with the resulting value.

**Usage**

```
lhs %<>% rhs
```

**Arguments**

lhs	An object which serves both as the initial value and as target.
rhs	a function call using the magrittr semantics.

**Details**

The compound assignment pipe-operator, `%<>%`, is used to update a value by first piping it into one or more rhs expressions, and then assigning the result. For example, `some_object %<>% foo %>% bar` is equivalent to `some_object <- some_object %>% foo %>% bar`. It must be the first pipe-operator in a chain, but otherwise it works like `%>%`.

**See Also**

[%>%](#), [%T>%](#), [%\\$%](#)

**Examples**

```
iris$Sepal.Length %<>% sqrt

x <- rnorm(100)

x %<>% abs %>% sort

is_weekend <- function(day)
{
  # day could be e.g. character a valid representation
  day %<>% as.Date

  result <- day %>% format("%u") %>% as.numeric %>% is_greater_than(5)

  if (result)
    message(day %>% paste("is a weekend!"))
  else
    message(day %>% paste("is not a weekend!"))

  invisible(result)
}
```

---

%% *magrittr exposition pipe-operator*

---

### Description

Expose the names in lhs to the rhs expression. This is useful when functions do not have a built-in data argument.

### Usage

```
lhs %% rhs
```

### Arguments

lhs	A list, environment, or a data.frame.
rhs	An expression where the names in lhs is available.

### Details

Some functions, e.g. `lm` and `aggregate`, have a data argument, which allows the direct use of names inside the data as part of the call. This operator exposes the contents of the left-hand side object to the expression on the right to give a similar benefit, see the examples.

### See Also

[%>%](#), [%<>%](#), [%%](#)

### Examples

```
iris %>%
  subset(Sepal.Length > mean(Sepal.Length)) %%
  cor(Sepal.Length, Sepal.Width)

data.frame(z = rnorm(100)) %%
  ts.plot(z)
```

---

%>% *magrittr forward-pipe operator*

---

### Description

Pipe an object forward into a function or call expression.

### Usage

```
lhs %>% rhs
```

**Arguments**

lhs	A value or the magrittr placeholder.
rhs	A function call using the magrittr semantics.

**Details****Using %>% with unary function calls**

When functions require only one argument, `x %>% f` is equivalent to `f(x)` (not exactly equivalent; see technical note below.)

**Placing lhs as the first argument in rhs call**

The default behavior of %>% when multiple arguments are required in the rhs call, is to place lhs as the first argument, i.e. `x %>% f(y)` is equivalent to `f(x, y)`.

**Placing lhs elsewhere in rhs call**

Often you will want lhs to the rhs call at another position than the first. For this purpose you can use the dot (`.`) as placeholder. For example, `y %>% f(x, .)` is equivalent to `f(x, y)` and `z %>% f(x, y, arg = .)` is equivalent to `f(x, y, arg = z)`.

**Using the dot for secondary purposes**

Often, some attribute or property of lhs is desired in the rhs call in addition to the value of lhs itself, e.g. the number of rows or columns. It is perfectly valid to use the dot placeholder several times in the rhs call, but by design the behavior is slightly different when using it inside nested function calls. In particular, if the placeholder is only used in a nested function call, lhs will also be placed as the first argument! The reason for this is that in most use-cases this produces the most readable code. For example, `iris %>% subset(1:nrow(.) %% 2 == 0)` is equivalent to `iris %>% subset(., 1:nrow(.) %% 2 == 0)` but slightly more compact. It is possible to overrule this behavior by enclosing the rhs in braces. For example, `1:10 %>% {c(min(.), max(.))}` is equivalent to `c(min(1:10), max(1:10))`.

**Using %>% with call- or function-producing rhs**

It is possible to force evaluation of rhs before the piping of lhs takes place. This is useful when rhs produces the relevant call or function. To evaluate rhs first, enclose it in parentheses, i.e. `a %>% (function(x) x^2)`, and `1:10 %>% (call("sum"))`. Another example where this is relevant is for reference class methods which are accessed using the `$` operator, where one would do `x %>% (rc$f)`, and not `x %>% rc$f`.

**Using lambda expressions with %>%**

Each rhs is essentially a one-expression body of a unary function. Therefore defining lambdas in magrittr is very natural, and as the definitions of regular functions: if more than a single expression is needed one encloses the body in a pair of braces, `{ rhs }`. However, note that within braces there are no "first-argument rule": it will be exactly like writing a unary function where the argument name is `"."` (the dot).

**Using the dot-place holder as lhs**

When the dot is used as lhs, the result will be a functional sequence, i.e. a function which applies the entire chain of right-hand sides in turn to its input. See the examples.

## Technical notes

The magrittr pipe operators use non-standard evaluation. They capture their inputs and examines them to figure out how to proceed. First a function is produced from all of the individual right-hand side expressions, and then the result is obtained by applying this function to the left-hand side. For most purposes, one can disregard the subtle aspects of magrittr's evaluation, but some functions may capture their calling environment, and thus using the operators will not be exactly equivalent to the "standard call" without pipe-operators.

Another note is that special attention is advised when using non-magrittr operators in a pipe-chain (+, -, \$, etc.), as operator precedence will impact how the chain is evaluated. In general it is advised to use the aliases provided by magrittr.

## Examples

```
# Basic use:
iris %>% head

# Use with lhs as first argument
iris %>% head(10)

# Using the dot place-holder
"Ceci n'est pas une pipe" %>% gsub("une", "un", .)

# When dot is nested, lhs is still placed first:
sample(1:10) %>% paste0(LETTERS[.])

# This can be avoided:
rnorm(100) %>% {c(min(.), mean(.), max(.))} %>% floor

# Lambda expressions:
iris %>%
{
  size <- sample(1:10, size = 1)
  rbind(head(., size), tail(., size))
}

# renaming in lambdas:
iris %>%
{
  my_data <- .
  size <- sample(1:10, size = 1)
  rbind(head(my_data, size), tail(my_data, size))
}

# Building unary functions with %>%
trig_fest <- . %>% tan %>% cos %>% sin
```

```
1:10 %>% trig_fest
trig_fest(1:10)
```

---

`%T>%`*magrittr tee operator*

---

## Description

Pipe a value forward into a function- or call expression and return the original value instead of the result. This is useful when an expression is used for its side-effect, say plotting or printing.

## Usage

```
lhs %T>% rhs
```

## Arguments

<code>lhs</code>	A value or the magrittr placeholder.
<code>rhs</code>	A function call using the magrittr semantics.

## Details

The tee operator works like `%>%`, except the return value is `lhs` itself, and not the result of `rhs` function/expression.

## See Also

`%>%`, `%<>%`, `%%$%`

## Examples

```
rnorm(200) %>%
matrix(ncol = 2) %T>%
plot %>% # plot usually does not return anything.
colSums
```
